[Faint, mirrored text, likely bleed-through from the reverse side of the page]

LONDON:
M'GOWAN & CO., STEAM PRINTERS,
GREAT WINDMILL STREET,
HAYMARKET.

6749

CONTENTS.

VOLUME VIII. JUNE TO DECEMBER, 1869.

A

Aberdeen dispensary, 432
 Absorption bands of bile, 346
 Abstracts of Introductory Lectures :—
 St. George's, King's College, Middlesex, St. Mary's, 297
 Accommodative asthenopia, 134
 Acna rosacea with hypertrophy of the nose, 133
 Aconite in tetanus, 170
 Action of hydrochloric acid on morphia, 128
 Acute orchitis, 38
 Action of boiling fluids on glass, 382
 Address to Dr. Dickie, of Alloa, 309
 Address to Dr. Sanders, 151
 Admission of ladies to medical classes, 419
 Admission of pauper patients into hospital, 490
 Albumen, 461
 Alcohol in large doses in poisoning by mushrooms, 100
 Amputation of a lion's tail under chloroform, 47
 An important discovery, 464
 Analytical report on Dublin XXXX porter, 478
 Anomalous accouchement, 376
 Antidote for haschisch (Polli), 494
 Antidote, the, 27
 Aphonia, hysterical, 521
 Association of medical officers, 408
 Atrophy of the heart, 134

B

Bed-sores on sacrum or nates, on a sling for treatment of, when patient is obliged to rest in the recumbent position (Porter), 453
 Belladonna and opium, on the antagonistic action of (Kavanagh), 116
 Boiling of liquids, 186
 Books received, 21
 "Bosch," 394

Brazilian antidote against the bites of venomous animals, 217
 Bromide of potash in dentition, 145
 Bromide of potassium in typhus fever, 394
 Buboes and their treatment by means of carbolic acid and small vertical incisions (Lamprey), 71

C

Calabar bean in trismus neonatorum, 163
 Camp at Colchester, 338
 Camphor as a preventive of oxidation, 68
 Cannibalism, 218
 Cantharides in cholera, 245
 Carbolic acid soap, 308
 Carbolized dry earth, 461
 Carbonic acid exhaled, 133
 Carolina twins, the, 133
 Catholic university of Ireland, 130
 Calculus successfully removed from the kidney (Annandale), 93
 Cases in which hypodermic injection was employed with good results (Barclay), 433, 509
 Causative agency of the skin and liver in the induction of phthisis and other scrofulous maladies (Luther, F.), 120
 Cerium in dyspeptic, on oxalate of (Lucas), 94
 Charing-cross hospital, 68
 Chair of clinical surgery and the university of Edinburgh, the, 35
 Chloroform, 498
 Chlorous acid, 461
 Chronic dysentery, 134
 Cienta virora, 186
 Clever lunatic, a, 69
 Clinical remarks on cases at the London hospital (Adams, J.), 319
 Cocoa—the public press and trade advertisements, 345
 Complete absence of anus with rectum opening into vagina (Garland), 182
 Concentrated tar solution, 68

Congenital artificial anus at the umbilicus, 134
 Consumption hospital, 452
 Consumption in Brazil, 217
 Contagious diseases act, the, 127
 Contagious diseases act in garrison towns, the, 156
 Contagious diseases act, remarks upon the (Worth), 512
 Control of prostitution, a plea for the (T. C. S.), 50
 Country practice, cases in (Willan), 52
 Copaiba and cubebs in croup, 187

CORRESPONDENCE.

"A. B." on naval assistant surgeons and their privileges, 393
 "A. G. L." on large families, 374
 "A Constant Reader" on the causative agency of the skin and liver in the induction of phthisis and other scrofulous maladies, 197
 "A Dispensary Doctor" on large families, 448
 "A Layman" on large families, 448
 "An M.A., F.R.C.S." on large families, 504
 Arnold, Eliza, on women physicians, 525
 Azygos on uterine rheumatism, 153
 Bernard, W., on local *versus* continental healthresorts, Rathmullan, co. Donegal, 152
 Biddle, D., on the propagation of the species, 356, 430
 Birchenall, J., on Professor Owen's idea of the soul, 44
 Bull, W., on the population question, 91
 "Cerebrosus" on the death of Mr. Justice Hayes, 508
 "Crom a Boo" on vaccination, 258
 Curran, J. W., on prostitution and its causes, 66; on uterine rheumatism, 215

- Davies, M. L., on nitrous oxide as an anæsthetic, 505
- Dr. Birch and the review of his work on oxygen, 489
- Drysdale, C. R., on the population question, 91; on large families, 413, 504
- Duggan, J., on female physicians, 506
- "F. A. S. L." on the multiplication of mankind, 375
- "F. L." on large families, 449
- Furnell, F. W., on a new method of extension in fractures of the femur and in coxalgia, 197
- Hare, F. A. C., on life assurance, 315
- "J. D. M." on large families, 356, 412
- Johnson, R. L., on the medical council, 216
- Johnson, Z., on treatment of fractures of the thigh by weight and pulley, 66
- "Justitia" on large families, 470
- Keen and Co. on mustard and its volatile oils, 177
- Kinkead, R. J., on prostitution and its causes, 19
- "L. T. H." on large families, 524
- Levy, H. J., on Dr. Ewing Whittle v. Dr. C. R. Drysdale, 65
- Luther, F., on the causative agency of the skin in the induction of phthisis and other scrofulous maladies, 276, 507
- "M. D." on quarantine, 337
- "M. D. Edin." on physicians and surgeons, 336
- "M. D., M. R. C. P." on the fee question, 277
- MacCormac, H., on cocoa and cocoa mills, 153
- MacCormac, Henry, on the prophylaxis of Asiatic cholera, 393
- MacCormac, H., on consumption in Iceland, 506
- Mapother, E. D., on the purchase of hospital offices, 67
- Martin, J., contribution to the statistics of operative surgery, 67; on the corporations and the medical council, 154; on deteriorated vaccine lymph, 505
- Martin, J. W., on continued extension in the treatment of fractures without using the pulleys and weights, 130; does the existence of any form of matter as a solid, a liquid, or a gas, depend upon the varying electrical conditions of its component particles or molecules? 431
- "Medicus" on large families, 414
- Mulvany, John, on the causative agency of the skin and the liver in the induction of phthisis and other scrofulous maladies, 449
- Murphy, J. R. M., on the population question, 43; on spectrum analysis, 111
- Muter, John, on hospitalism, 337
- Nourse, W. E. C., on large families, 447
- O'Flynn, D. B., on the medical council, 196
- O'Donovan, W., on chloroform, 45
- O'Kelly, R., on premature labour, 176
- "Oh! Exclamantis" on the college of physicians of London, 507
- Phelan, D., on a poor-law medical officers' widows and orphans society, 431
- "Physiologist" on large families, 449
- Podalirius on the *Lancet* again, 295
- "Practitioner" on large families, 469
- "Prudentia" on large families, 295, 393
- "Q." on therapeutics v. quackery, 524
- Red tape—how not to do, 67
- Rivington, W., on the appointment of assistant surgeons to the London hospital, 316
- Smith, F., on carbolic acid oil in scarlatina, 431
- Smith, H. J., on weight and pulley, 45
- Stephens, W., on the point of alliance between puerperal fever and scarlatina, 215
- "T. C. D." on large families, 470, 504
- "The reviewer's" reply to Dr. Birch, 490
- Wilmot, S. G., on the systems of election to medical appointments in the Dublin hospitals, 42, 92
- Cruelty to a lunatic, 156
- Crural hernia, operation for, 145
- Curare, properties of, 117
- Cyanide of potassium, poisoning by (Hallin), 202
- D
- Danger of giving strong doses of camphor, 258
- Death by electricity, 123
- Decolourization of tincture of iodine, 178
- Deteriorated vaccine lymph, 505
- Diagnosis of chancres, the, 347
- Diagnosis of diseases of the spine, 277
- Diphtheria, the use of carbolic acid in the treatment of (Leeper), 260
- Diseases of the heart and aneurism in the royal navy and army (Robertson), 7
- Dislocation of the atlas forward (Ridley), 140
- Dislocation of the femur on the dorsum of the ilium of a few hours' duration, reduced by flexion and rotation outwards, 439
- Dr. Aitken, the late, 432
- Dublin military prisons, 111
- Dynamite, 19
- Dyspnoea relieved by the inhalation of oxygen, 308
- E
- Eatable clay from Java, 498
- Ectropium intestinum, 155
- Edinburgh royal college of physicians on the medical council, 125
- Edinburgh royal infirmary, 385
- Electricity for lessening pain in extracting teeth, 187
- Empress Charlotte, the, 112
- Endoscopic examination of the cavity of the womb (Pantaleoni), 26
- Enlargement of the papillæ in lichen ruber of Hebra, 133
- Ergot in facial neuralgia, 134
- Ergot of rye as a therapeutic agent (Waring-Curran), 397, 527
- Ergot in the treatment of purpura, 134
- Ergote, on a new liquor (Long), 435
- Ergotine in diarrhoea and dysentery, 394
- Erysipelas, notes on some cases of (Martin, J. W.), 301
- Ether spray, treatment of chorea by, 155
- Ethyl-hyposulphurous acid, 186
- Examining bodies whose examinations fulfil the conditions of the medical council as regards preliminary education, 14
- Excessive secretion of the liquor amnii, producing premature labour, 278
- Exit of a pin swallowed five years before (Chain, A.), 97
- Experiences of a regimental surgeon in India (Gordon, C. A.), 3, 49, 137, 243, 285, 359, 415
- Extension in fractures of the thigh by means of a weight and pulley (Thompson), 121
- Extensive saw wound of the skull, extraordinary recovery from, 525
- Extern maternities and lying-in hospitals, a reply to criticisms on a communication to the Dublin Obstetrical Society, 131, 141, 161, 194, 213, 256, 263, 293, 306, 326, 355, 364, 402
- Extirpation of the uterus, 83
- F
- Facial neuralgia, a frequent cause of, 133
- Feeding bottle, the new infants', 317
- Female medical education in Sweden, 60
- Female medical students, 406
- Fin whale, the, 517
- Fluorescence of quinia, 18
- Forced and prolonged flexion of the limbs in traumatic hæmorrhage, 212
- Formation of fungoid growths in milk, on the, 203
- Fracture of skull, 111
- Fracture of the scapula, 327
- G
- General practice, cases in (Watson), 381
- Glasgow infirmary, 151
- Gleanings in medicine, surgery, and the allied sciences, 68, 111, 132, 154, 177, 178, 216, 217, 257, 258, 277, 278
- Glossitis treated successfully by magneto-electricity, 454
- Glycerate of tar, 526
- Goitre cretinism, 97
- Graduation ceremonial at the university of Edinburgh, 125
- Glasgow and Aberdeen universities, 354
- Grubkiller, a cheap, 349
- Guy's hospital, 527
- H
- Hæmorrhagic malaria, 385
- Harvard university, 218
- Haschisch in hydrophobia (Polli), 476
- Hedgehog, peculiarities of the retina of the, 19
- Hermithology, on (Gaskoin), 157
- HOSPITAL REPORTS.
- Coombe Lying-in Hospital.—Uterine hæmorrhage for 12 months, dependent on fibrous polypus of uterus; removal by écraseur, under Dr. Kidd, 9; hæmorrhage from uterus, accompanied by great pain; soft polypus exposed by tents of sea-tangle, and removed by écraseur—uterus swabbed with strong nitric acid, under Dr. Kidd, 30
- Jervis street Hospital.—Enormous hypertrophy of breasts, necessitating removal of one organ, the operation followed by the reduction in size of the remaining breast, under Mr. Mulligan, 158; fracture of patella, under Mr. Stapleton, 159; blood poisoning and inflammation of lymphatics, tonic treatment, under Mr. Stapleton, 182

Meath Hospital and County Dublin Infirmary.—Importance of rounding the edge of the tibia in amputation of that bone, femoro-popliteal aneurism treated by compression, under Mr. Porter, 30, 54; nævus cured by injection of carbolic acid, enlargement of a mouth previously contracted by the operation for the cure of hare-lip, under Mr. Porter, 141; bloody tumour of scalp treated by free incision, under Mr. Smyly, 141; case of lateral lithotomy, under Mr. Mayne, 262; removal of adenoid tumours in axillar, under Mr. Wharton, 263; Symes's amputation through the condyles of femur, for old-standing disease of knee-joint, different modes of operating for the cure of anal fistula, amputation of penis for epithelial disease, —Ricord's operation, 322; case of hydrophobia, under the care of Mr. White, 381

Mercer's Hospital.—Varicose state of saphena veins, erectile tumour of the forehead, external hemorrhoid treated successfully by the injection of persulphate of iron, under Mr. Morgan, 28; hereditary syphilis, under Mr. Morgan, 100; case of contracted mouth operated upon successfully, under Mr. Morgan, 159; local syphilitic paralysis, under Mr. Morgan, 204; fracture of the patella, 245

Royal Free Hospital.—Extraction of a fibroplastic tumour from the neck, 513

Metropolitan Free Hospital of London.—Cases under the care of Dr. C. Drysdale and Mr. Warner, 322; cases of stricture, 399, 455; absence of spermatozoa, 513

Royal London Ophthalmic Hospital, Moorfields.—Case of double cataract, double lenticular cataract, case of "Grave's disease," staphyloma of the left eye, 340; excision of the cornea, double congenital cataract, double divergent strabismus, 360; amaurosis, 399; case of astigmatism, paralysis of all the muscles of the orbit of the left eye, 436; case of episcleritis, dilated sac and obstructed duct, interstitial keratitis, dislocated lens, 495

Royal Victoria Hospital.—Aneurism of thoracic aorta, death from exhaustion, 244; aneurism of thoracic aorta, causing a tumour under left scapula, aneurism of abdominal aorta, distinct syphilitic history, death from gradual hæmorrhage, 302; case of abscess of the liver excavated by Bowditch's syringe, rapid recovery, abscess of liver, discharging through right lung, inhalation of carbolic acid vapour, abscess of the liver discharging externally, carbolic acid injection, 361; abscess of the liver, discharging outwardly, 400; enlarged spleen, 456

University College Hospital.—Operation for aneurism, by Mr. Erichsen, 360; popliteal aneurism, 399; cases under the care of Dr. Ringer, 513

Westmoreland Lock Hospital.—Hereditary syphilis cases under Mr. Morgan, 76; laryngo-tracheotomy, under Mr. McDowell, 263

Workhouse Hospital, Galway.—Case of chorea from membranous inflammation of intestine, under Dr. Cleland, 77

Hospital tents, 218

Hydatids, 112
Hydatid cyst in the brain, 187
Hydrated silicate of magnesia, 460
Hydrophobia, 244
Hypertrophy of one half the body, 267
Hypodermic injections of morphia in labour, 112

I

Idiopathic tetanus (Clarke, T. E.), 119
Ice in affections of the testicles, 20
Imperforate hymen, 477
Impermeable stricture of the urethra, 79
Incontinence of urine, 461
Increase of pauperism, 198
Indian medical service, 187
Indian prisons, 526
Indian transport service, 503
Indirect osteoplasty, 154
Information relative to medical students:—Regulations of the licensing bodies and of the schools of medicine—Oxford and Cambridge universities, 220; University of London, 220; University of Durham, 220; Royal College of Physicians, London, 221; Royal College of Surgeons of England, 221; Apothecaries' Society of London, 221; Irish hospitals and schools of medicine, 222-224; Provincial Colleges of Ireland, 224; regulations and by-laws of licensing bodies in Ireland, 224-228; Scottish institutions, 228-230; educational institutions in London, 230-232; Provincial English Schools, 232-233; public services, 235-239; surgeonies in the mercantile marine service, 240
Influence of climate on venereal diseases, 163
Influence of cold, the, 257
Influence of pressure on chemical phenomena, 19
Injection of putrid matter, 367
International flag, 218
International medical congress at Florence, 303
Introduction of the clamp in ovariectomy, 135
"Intussusception," report of a case of (MacSwiney), 511
Inventions:—Richardson's splint for the treatment of fractures of the clavicle, scapula, and neck of humerus, 496; new fracture apparatus, 496
Iodine and aconite in periodontitis, 165
Is nitric acid formed during a thunder storm? 461
Is valerian an antidote for strychnia? 308

J

Jaundice, on an epidemic visitation of (Hayden, T.), 4

L

Lady doctors, 78
Large families, 43, 91, 295, 356, 374, 375, 393, 412, 413, 414, 430, 447, 448, 449, 469, 470, 504, 505, 524
Last illness of the Czar Nicholas, 156
Leading articles in the "Journal of the British Medical Association" (Leared, A.), 139

LECTURES.

Address delivered at the University of Edinburgh, 377

Burrows', Dr., address at the opening of the Session of the General Medical Council, 1
Consideration of ritualism, with reference to its influence on insanity, 201
Fibrous tumours of the uterus, 24
Introductory lecture delivered at the London Hospital Med. School, 279
Lecture—Introductory to the course of general pathology at Edinburgh University, 395
Lee, Mr. Henry, on the obliteration of varicose veins, 471
Lister's opening lecture at the University of Edinburgh, 397
Macleod, Dr., introductory lecture delivered at the Glasgow University, 473
Midwifery practice, on the use of the forceps in, 179, 199, 241
More-Madden, T., on the use of the forceps in midwifery practice, 179, 199, 241
Report of the inaugural address delivered at the opening of the winter session of the united College of St. Andrews, 379

LEADING ARTICLES.

Female physicians, 10
Purchase of hospitals, the, 32

Baby farming, workshops' regulation act, compensation for railway injuries, toxicology extraordinary! the nature and treatment of cholera, health of Dublin, Queen's University in Ireland, mortality among German troops, statistics of suicide in Continental armies, 125-127
The Medical Council, the introductory, army report, leaf evaporation, the lunacy report, new act on Greenwich Hospital, native Indian surgeons, after the dust-bin, "quiet and private," of course, medicine and surgery in Japan, the health of Mr. Gladstone, a rational statement on water-supply, injection of ammonia into the veins in snake bite, penalty for infringement of the vaccination act, poisoned by laburnum seed, cholera in Poona, Autumn complaints, Sir J. Gray, M.P., and medical reform, Coroner's work, outbreak of cattle disease in Surrey, public mortuary for the East of London, 146-150
Trinity College, Dublin, vaccination in India, ammonia as an antidote for snake poison, the cattle plague, the Indian Pharmacopœia, health of Dublin, the fever haunts of India, a Poor-law Medical Officer and the Guardians, the sanitary condition of the Suez Canal, an International Pharmacopœia, the water commission, social science, 163-170
The fall of the "Albert," Indian medical service, health of the Emperor of the French, the great water question, rural sanitary measures in India, the New York drug bill, deaths by violence, Jonathan Hutchinson, Esq., Ed. B. M. J., Professor Halford's treatment of snake bites, alarming symptoms in consequence of wasp stings, the Female Physicians at the Philadelphia Hospital, Chinese consumption of opium, poisonous odours, 190-193
The epidemic diathesis in America, modern homœopathy, the late G. W. Mackmurdo, F.R.S., St. Bartholomew's Hospital, Queen's College, Birmingham, Devon and Exeter Hospital, Budleigh Salterton, 209-210
Indigenous foods in India, the contagion of dog mange, deaths of passengers on Indian railways, the nerves of deglutition, the London Hospital, sanitary condition of Calcutta, the mortality of cholera, snake poison, chloral, St. Bartholomew's Hospital, Women's Medical Mission, Charing-cross Hospital, the Medical Officer of the Privy Council, the Newport poisoning case, luc-

nacy in France, outdoor relief, the vaccination question, Dr. Pettenkofer's cholera theory, cholera in India, 250-255

The cause of heart disease in the army, the late Dr. Roget, F.R.S., scarlet fever, the scandal at St. Bartholomew's Hospital, the London Hospital, Charing-cross Hospital, dissecting room fees in Trinity College, Dublin, the development of the cerebellum in the insane, snake poisons, transmission of disease by vaccination, compulsory vaccination in Bombay, the collapse of the European Life Office, convict labour, cheap ice, the German Scientific and Medical Association, Indian cholera, hospital subsidies in France, 271-275

The Baddesley Endors murder, transfusion of the heart without death, practical *v.* theoretical surgery, Mr. F. W. Newman's idea of the profession, the perils of petroleum, the effects of transfusion of blood, the Medical Club, the new hypnotic, cholera in the Punjab, the London Hospital, the stamping-out of small-pox in Ireland, the opening of the London Medical Schools, latest intelligence with a vengeance! election of assistant-surgeons at the London Hospital, Scotch Universities, 289-293

The opening at Netley, the heat in India, medical annuities in India, compulsory vaccination, large families, poisoned by hair dye, abuses of vivisection, threatened aggregation of vaccino-maniacs, pauperism in Scotland, the hospital dinners, St. Bartholomew's Hospital, the late Surgeon-Major S. H. Batson, American medical missionary in China, asylums for inebriates, health of Dublin, dangerous ground, a pleasurable reminiscence, Californian bathing geysers, election of assistant-surgeons at the London Hospital, life assurance, medical examination of recruits, vaccinomanic logic, Alpine desagrégemens, the milk of diseased cows, proposed Hospital for Incurables, near Oxford, the Fothergillian Prize, 309-315

Diseased meat, Indian native midwives, medical and hospital reforms, fever at Chippenham, Poor-law Medical Officers' Association, anti-vaccinating madness, copper as a cure for cholera, nursery reform, Charing-cross Hospital, clinical examinations at the Queen's University, the tactics of the vaccinomanics, death from bichloride of methylene, removal of the dead, chloral, infant mortality in France, cattle typhus in Sicily, hospitals and asylums in France, 330-334

St. Bartholomew's Hospital, the late Lord Derby, Royal College of Surgeons of England, the London schools, still St. Pancras, a new double diploma, work me to death and I will be grateful, railway reform, scarlet fever, cruelty to horses, cholera and the sanitarium in India, gratuitous medical services in the Indian army, clerical patrons of venereal, University of Oxford, health of Dublin, 350-352

The Medical Council, English and Irish Poor-law Service, mortality of the quarter, vaccino-phobia, the University of Cambridge and the Medical Council, University College Hospital, composition of Portuguese beef, eating

hair, proposed medical mission for London, the cholera at Peshawur, scarlet fever at the Children's Hospital, Mr. Peabody, representation of the Universities of Glasgow and Aberdeen, 371-373

General Medical Council, British corn flour, never say die! International standard measures, health of Dublin, the digestive powers of pancreatine, the profession as a trade, Dr. Richardson's lectures, Natural History Society of Ireland, Dr. Rattray on the diet of seamen, extension of the contagious diseases act, St. Bartholomew's, new chemical nomenclature, the inauguration of Dupuytren's statue, 388-392

Registration of disease, the black hole of St. Pancras, certificates of death, the preference of paupers for vitiated air, treatment of epilepsy by M. Bost, at Les Asiles de la Force, Dordogne, France, Medical and Chirurgical Society, Society for Relief of Widows and Orphans of Medical Men, Sir James Alderson, M.D., deaths from chloroform, the Birmingham Training Institution for Nurses, address to Dr. Mulligan, of Flurry Bridge,—reply; a miraculous doctor, cholera sources in the East, 407-408

Society of Apothecaries of Ireland, health of Dublin, a female student at the Dublin Medical Schools, the climate of Victoria, a novel method of treating naso-pharyngeal polypi, by M. Bonnes, treatment of canceroid growths by arsenic, syphilitic paralysis treated by mercurial inunctions, communicability of "charbon" by the common fly, the non-degeneration of vaccine virus, Dialectical Society of London, chairs of hygiene, Professor Huxley, special hospitals, admission of Licentiate to the Fellowship of the Royal College of Surgeons, Ireland, a new phase in legal psychology, St. Bartholomew's Hospital—special general court, is anything being done? Mr. Griffin, apoplexy and drunkenness, Hospital for Women in Soho square, Miss Nightingale, relapsing fever, St. Pancras again, the Mansfield Guardians, epidemic fever in East London, the cholera at Peshawur, chloral, pharmacy in Ireland, Chinese therapeutics, 424-429

Purchase of hospital appointments, Sir P. Dun's Hospital and the monopoly of education in Dublin, lunatics, idiots, and cretins in France, doctresses in America, meat preserving, the Dublin Pathological Society, University of Edinburgh, the elysium of quackery, the prevention of syphilis, "quietness" again, a cholera charnel house, transfusion of blood in traumatic fever, lady students at Edinburgh, St. Pancras Infirmary inquests, the late Dr. Locking, the prescription copyist, Royal College of Physicians of London, the profession as a trade, opinions of the journals on Mr. Foster White's speech, Hospital for Women in Soho square, a hundred patients per hour, Royal Sea-Bathing Infirmary, Royal Hospital for Incurables, the Poor-law Board Inspectors, Dr. Karr on Health and Disease, viewed in relation to the opinions of Darwin (Malthus); with illustrative cases, the Medical Teachers' Association, unqualified medical practitioners, women doctors, 441-446

Mania-a-potu, the Archbishop of Canterbury, recent researches on artificial tuberculosis, death from descending a well, admission of pauper patients into hospitals, the proposed Royal Society of Medicine, Lincoln County Hospital Centenary, unique and remarkable case of extra-uterine foetation, syphilitic gummatous deposit in the lungs, varicose dilatation of lymphatics, a displaced spleen causing symptoms of strangulated inguinal hernia, Swedish lady doctors, the latest mesmeric feat! the repression of mendicity, Surgical Aid Society, the Parisian Medico-Legal Society, "sweet quinine," insanity in America, a new direction for medical literature, cheap meals for the poor, Royal Medical and Chirurgical Society, 466-469

The Surgeon Extraordinary to the Queen in Ireland, the theory of poisoning by phosphorus and pyrogallic acid, remarkable injury of the head, the "dry earth" method in court, immigrants into the States, verdicts of coroners' juries, causes of mortality among the children of the poor, contagious diseases act of 1866, the Southampton Infirmary, another piece of "medical charity," gratuitous services in hospitals, Royal Institution, the visiting list, the doctor's little bill, the Metropolitan Free Hospital, a "large family," relapsing fever and the Jews, imperforate hymen, relapsing fever, law court ventilation, the Sharpey memorial, hospital-nurses, Dr. Barnes on uterine hæmorrhage, repression of contagious diseases, 483-487

French hospital and dispensary, Highgate Workhouse Infirmary, abolition of University tests, Blackheath Mendicity Society, the Surgeon in Ordinary to the Queen in Ireland, unlicensed doctoring in America, spiritualism, the new military barracks in India, death of Dr. Bryson, health of Napoleon III., liability of consultants for the fees of consultees, a cheap way of doing the doctor, the Welsh fasting girl, 500-502

Medical reform, death of Professor Geoghegan, of Dublin, hysteric aphonia, proposed Royal Society of Medicine, vaginismus, the health of Ireland, "Dark Sam, the Medical," Medical Society of London and athletic sports, 520-522

Address

BY

DR. BURROWS, F.R.S.,

President of the General Medical Council,

AT THE

OPENING OF THE SESSION ON JULY 1.

GENTLEMEN,—I shall venture to trespass upon you for a few minutes before we proceed to the public business of the session. The interval between our two sessions has been somewhat longer than usual, because no pressing public business has compelled me to summon you hither at a season when I know it would have been particularly inconvenient to many of you to leave the seats of your public and private duties. Now, if the recess has been somewhat longer than usual, it certainly has by no means been a period of inactivity and leisure to the majority of the members of this Council. It is in the remembrance of you all that at our last meeting, we appointed two very important and numerous committees—the Committee upon Medical Education, and the Committee upon State Medicine, and these committees have continued their labours throughout the interval. These committees comprise no less than fourteen members of our body, and of the labours of these committees I can speak officially,—not that I have joined in their labours, or am taking credit for any part of them, but I have been officially cognisant of their labours,—these labours have been excessive, and continued throughout the recess up to the very hour of our assembling in this hall. These committees have collected a vast amount of information to elucidate the subjects they were appointed to inquire into. The materials, being collected from various sources, were no doubt of very unequal value—very heterogeneous, we may say,—and perhaps in some points they are actually discordant, so that it must unquestionably require great discrimination and labour to winnow the produce, to separate the grain from the chaff, and to draw up reports which will form the basis for future action. Let us hope that the gain which is to be realised by the reports of these committees may be in some degree commensurate with the great—and I ought to add gratuitous—labours of the members of these committees, and likewise, I would say, with

the probable heavy expense which will be entailed upon this Council in collecting the materials, and also embodying the information contained in printed reports. Gentlemen, among the duties delegated last year to the Executive Committee, was the responsible one of communicating with the Government upon the amendment of the Medical Act of 1858. When this question was brought before the Executive Committee, I thought it right to press upon their attention the views that I expressed to this Council at the opening of the last session. I am not going to detain you with a vain repetition of those remarks, but the gist of them was to this effect,—that it was more within the province of the President of the Privy Council than of the Home Secretary, to undertake the required legislation to amend the Medical Acts, inasmuch as the Privy Council and the Medical Council have been associated together by the Legislature in the working of the Act of 1858; and, moreover, that it appeared to me that there was a greater probability of successfully initiating medical legislation in the House of Lords than in the House of Commons. The Executive Committee adopted my suggestions, and appointed a deputation of their body to wait upon the President of the Privy Council. That deputation consisted of your Treasurer, Dr. Sharpey, Mr. Caesar Hawkins, the Registrar, and myself. Our deputation was received by Lord Grey and Mr. Forster, the President and Vice-President of the Committee of Education of the Privy Council, and these Ministers were attended by the Clerk of the Council, Mr. Arthur Helps, and the medical officer of the Council, Mr. Simon. As your President, I had then an opportunity of bringing before the Government the reasons why we applied to the President of the Privy Council for his assistance in Parliament, and of pointing out the increasing and urgent necessity there was for some amendment of the Medical Acts. My report of the result of the deputation unfortunately is very similar to that which I have had to make upon former occasions; in fact, the account of it might almost be stereotyped: "Courteous reception, attentive, and apparently willing, listening to a rather long statement of many arguments, and this ending by the expression of profound regret that the pressure of public business would not allow of medical legislation in the present Session." After some little further pressure on my part on the President of the Privy Council, I subsequently received a letter, a very important one, from the medical officer of the Privy Council, written by direction of the Lord President, announcing the intention of the Government to go, during next Session of Parliament, more deeply into the question of

medical legislation than the mere amendment of the Medical Act of 1858, as had been suggested by this Council. This letter will almost immediately be laid before you, and you will find in it suggestions which will require careful and, I fear, very prolonged consideration on your part. On Monday next you will be called on to exercise one of the most delicate and responsible functions which have been entrusted to you by the Legislature; you will have to decide whether an individual whose name is upon the Medical Register has been guilty of infamous conduct in any professional respect, so as to preserve the erasure of his name from the Register. This function, gentlemen, must always be exercised with the greatest prudence, and only under the advantage of sound legal advice. The Legislature has not thought proper to trust us with power to arrest the practice of notorious quacks and medical impostors, but it behoves this Council to exert its powers, and to purge the Register of the names of the persons whose conduct is more in accordance with the proceedings of quacks, and vendors of nostrums, than of educated professional gentlemen. Should the facts of this case to be laid before you not warrant the extreme sentence of expunging the medical practitioner's name from the Register, I feel sure the discussion on the merits of the case will have a beneficial influence in a moral point of view, and will assure the members of the profession at large that this Council does not timidly shrink from the performance of a painful and sometimes invidious duty. No public body in this country is or ought to be exempt from criticism, either by the press or other modes of expressing opinion, and the Medical Council cannot expect to be an exception to the general rule. Those who only have an imperfect knowledge of the state of medical education, and the examinations carried on at the Boards of numerous licensing bodies when this Council first commenced its labours, can form no just estimate of the beneficial influence exercised by this Council upon medical education, both preliminary and professional, and upon examinations throughout the United Kingdom. It would be invidious and unbecoming on my part to advert to the improvements in any particular institution; but there must be few, I think, who would not candidly admit the value of suggestions made to them by visitors from the Council upon the modes of conducting examinations. The fruits springing from the good seed sown can hardly yet be appreciated, and cannot arrive at maturity until a new generation of practitioners has succeeded those who have gradually faded away. Because young men are still found to be imperfectly educated when put to the test of a searching examination, and particularly those examinations which are instituted for admission to the public services, it has been inferred that this Council have not done their duty, and have not brought the standard of education up to that point which we all should desire to see it attain. Those who arrive at such a hasty conclusion can know very little of the practical working of medical schools and other places of education. A system of education may be good, the teachers may be zealous and efficient, and highly informed, but regard must always be had to the materials that they have to work upon. Young men are now what they always have been, and what they probably ever will be. It matters not whether it be a public school, a university, or a medical college, a large number of those who are entered as pupils will not be students in the proper sense of the word. Some, no doubt, are below the average standard of intellect, some are indolent, some are devoted to athletic sports, although not wanting in ability, and of these several classes many must necessarily fail in examination; and those of such classes who are so fortunate as to pass will probably have gone through the ordeal of what is termed "cramming" in one place, and "coaching" in another. No doubt these evils are greatly to be deplored, but can they be overcome? Possibly they may be lessened. The Medical Council or any other public body authorised to issue regulations for educational examinations, have no special power to make all young men industrious and zealous in the acquisition of knowledge; and in my opinion all regulations and plans of education and defined modes of teaching will, if unaccompanied by other measures, always fail in making young men well informed in their profession. The most successful methods of accomplishing this desirable object, in my opinion, would be by the establishment of a good Examining Board, a conjoint Examining Board in each division of the United Kingdom (hear, hear), and by instituting examinations of such a nature as shall unquestionably ascertain the required amount of knowledge of each candidate for a licence to practise the medical profession. Although rules and regulations, and curricula of study, may be properly laid down for

the information and guidance of those who propose to offer themselves for examination, it will be, in my opinion, the examination, and that alone, which will establish the standard of knowledge among the candidates. According to the well-established law in free, civilised, and commercial countries, supply will always bear a direct relation to demand, and this law I believe will be found to apply to the conditions of medical education. If examinations are complete, efficient, and well-conducted, those who are desirous of passing them successfully will resort for instruction to those sources where they can most certainly obtain the thing that they are in need of. On the other hand, those who are anxious to collect about them a body of students must necessarily make such arrangements, and afford such instruction, as will enable industrious students to obtain the wished-for knowledge which is to enable them to pass a successful examination. I feel assured, then, it will not be by a fixed curriculum of study, with precise and defined methods of teaching particular branches of science, that the standard of knowledge among medical students will be eventually improved. Much liberty, I think, may and ought to be allowed in methods of teaching, and still more in methods of learning, and also in the details of the curriculum of study. I would say, only once establish a uniform good examination in each division of the United Kingdom for all medical students, and the standard of knowledge among them will soon correspond to the requirements of the Examining Board. From an experience, gentlemen, of ten years, as a member of this Council, and acknowledging, as I have frequently and publicly, the great improvements effected through our regulations and suggestions, I have nevertheless arrived at the conviction, that even if this Council were armed with more extensive and arbitrary powers, it would be impossible to accomplish all those improvements in preliminary and professional education and examinations at the various licensing boards which are required to ensure the qualification of all those admitted to practise the medical profession. The most simple and the most certain method, I think, of effecting this great object will be the establishment of one conjoint or public Examining Board for each division of the kingdom. I had determined on giving expression to these sentiments before I had the opportunity of perusing the draft Report of the Committee on Medical Education, and I am rejoiced to find that I have arrived, independently, at a conclusion similar to that embodied in the document above referred to. The observations in that draft report are very much to this effect, that the time has now arrived when giving universities and corporations full liberty to deal as they please with their honorary distinctions and degrees, the Medical Council should insist upon a conjoint Examining Board for each division of the kingdom, before which every person who desired a licence to practise should appear, and by which he should be examined upon all subjects of professional education. I certainly do think, and thinking it I feel bound to express my thoughts, that by this method a licence or diploma would be granted which would guarantee to the public (and we have to think of that) that every registered practitioner was properly qualified in every branch of medical knowledge. Gentlemen, if you refer to the printed programme which is before you, the programme for the business to be transacted at this meeting of the Council, you will find the list of agenda a very long one, and embracing very large and comprehensive subjects, which will require much deliberation, and will no doubt give rise to much discussion. As this seems inevitable, I would suggest in the interest of the whole Council, both of the members individually, and also of our body I may say financially, that we should have a tacit but well-understood agreement that each member, in addressing the Council, should honourably endeavour to condense his observations and his arguments as far as possible, and refrain from those digressions and illustrations which, however amusing, and, I admit, adding very much to rhetorical effect, have very little influence upon the judgment and decision of the "grave and reverend seigneurs" who sit around this table. Gentlemen, I hope that these remarks may not be regarded in any sense as personal. I offer them to you as a parting legacy to a friend. They are made solely as an *amicus curiæ*, with a desire to facilitate the transaction of the business of the Council, and also, if possible, with a desire of enhancing the reputation and authority of this Council with the profession and with the public out of doors.

Original Communications.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 496.)

FEVERS.

ON the subject of treatment, I note that while occupied in carrying out some official investigations relative to the comparative success of some reputed remedies, I preserved a record of a considerable number of cases in which quinine in various doses and combinations was administered; and from those records I have prepared the following summary, namely:—

Quotidian Intermittent.—One case in which no medicine was given was discharged recovered in twenty-two days.

One case, treated with 2 grains of quinine three times a day for six days (18 grains), recovered in eight days.

Of four cases treated by 3-grain doses, administered three times a day, one was so during three days, having a total of 27 grains, and recovered in nine days; two during five days, each taking in that time 45 grains; one of the two, being discharged, recovered in five days, the other in six days; and one treated thus for twenty-one days, taking \bar{z} j. grs. 45, was in hospital before recovery eighty-two days. Average, twenty-five days.

Of three treated by 3 grains of quinine and 1 of rhubarb, repeated three times a day, all were so during four days, taking 36 grains. One of these recovered in four days, the other in five, and the third in six. Average, five days.

One case treated by 3-grain doses, repeated four times a day during ten days, taking in that time \bar{z} ij. and 6 grains, was at the end of that time discharged recovered.

Three cases were treated by quinine in 5-grain doses, and of them the statistics are as follow, namely:—In one the quantity was administered uncombined three times a day during three days; 45 grains in all were taken, and the patient was discharged recovered in ten days. In two this dose was combined with 1 grain of rhubarb, and repeated three times a day; one patient so treated had \bar{z} j. and 15 grains of the remedy in five days, and was discharged in seven. In one it was similarly administered during four days, 23 grains being taken in all, and the patient discharged in nine days. Average, nine days.

In one case, after this dose and combination had been employed five days, quinine uncombined was given in 3-grain doses thrice during two days, \bar{z} j. grs. 33 being taken in that time, and the patient discharged recovered in nine days.

In another the combination was given three times a day during three days, three grains of uncombined quinine being administered thrice a day during two more; \bar{z} j. grs. 15 taken in all, and the patient discharged recovered in five days. Average, seven days.

One case was treated by 5-grain doses, in combination with 2 of rhubarb, every third hour during two days, and 3 grains of each three times a day during three more; the total quantity taken was \bar{z} j. grs. 15, and the patient was discharged in eleven days.

Five were treated with similar doses of quinine, combined with 3 grains of rhubarb, administered three times a day. In one of these the treatment was continued during three days, the patient taking 45 grains in all, and discharged in four. In one it was continued during four, the quantity taken being \bar{z} j., the patient discharged in sixteen. In two it was continued during seven, the quantity taken being in each case \bar{z} j. grs. 45. One of the patients was discharged in ten, the other in eighteen days; and in the fifth case the treatment was continued during

eight days, \bar{z} ij. of quinine was taken, and the patient discharged in thirteen days. Average, twelve days.

One patient had 5 grains of quinine and 3 of rhubarb repeated twice in one day, and 2 grains uncombined thrice a day during five; he took in all \bar{z} j. grs. 15 of the remedy, and was discharged in seven days.

Another had a similar combination three times a day during two days, and then 3 grains of quinine three times during one day; he took in four days 45 grains, and at the end of the time returned to duty.

In two cases the 5-grain dose of quinine was combined with 5 of rhubarb. In one of these this dose was repeated three times during one day, then varied by 1 grain of hyoscyamus being substituted for the latter, and so continued during four days. The patient took in all \bar{z} j. and 15 grains of quinine, and was discharged in thirty-five days. In the other the 5-grain doses of quinine and rhubarb were continued during three days, 3-grain doses of uncombined quinine being given for eight days more, making eleven in all. During that time \bar{z} j. grs. 27 of quinine were taken, the patient being discharged in eleven days. Average of the two, twenty-three days.

Three cases were treated by 10-grain doses of the medicine. Of these, one dose only was given in one case, no further treatment being employed, and the patient discharged recovered in sixteen days. In one the dose was repeated twice a day during two days, 40 grains being taken in that time, and the patient discharged in six days. In another the dose was given once a day during three days, \bar{z} ss. of the medicine being taken in all, and the patient discharged in five days.

In three cases one dose of 10 grains was given, and afterwards doses of 5 grains repeated three times a day; one of the patients so treated took \bar{z} j. grs. 14, one \bar{z} j. grs. 35, and the third \bar{z} j. grs. 40 of the remedy, each being discharged in eight days.

Two patients were treated by 10 grains of quinine administered as one dose, the remedy being afterwards administered in doses of 5 grains, with 1 grain of extract of hyoscyamus, repeated three times a day. Of these, one was so treated during four days, \bar{z} j. grs. 10 of quinine being taken, and the patient discharged in six days; the other during five, \bar{z} j. grs. 25 being taken, and the patient discharged in nine days.

One had a single dose of 10 grains, with 3 grains of blue pill, followed by doses of 3 grains of quinine repeated every four times. The patient was thus treated three days, took 45 grains of quinine, and was discharged in nine.

One, after having a single dose of 10 grains, was treated by 5-grain doses repeated three times during one day, a similar quantity being given, combined with 3 grains of rhubarb, three times a day during four days. In this case the treatment extended over six days, \bar{z} j. grs. 25 being taken during that time, and the patient discharged in eight.

Another man treated by 10-grain doses had two such, followed thereafter by 3-grain doses three times a day during three days; he took in all 37 grains, and was discharged recovered in six.

Quinine in doses of 30 grains was administered as follows:—In one case only one dose was given; no further treatment was employed, and the patient was discharged in six days. In one the dose was given on two consecutive days; \bar{z} j. was thus taken in all, and the patient discharged in four days. In one, after one dose of 30 grains, the medicine was given in quantities of 5 grains repeated three times a day during two days, and afterwards in doses of 2 grains three times a day during six days; this treatment was employed during eight days, \bar{z} j. grs. 36 of quinine being taken, and the patient discharged in ten days. In another two doses each of 30 grains were administered, followed by a scruple dose twice repeated, and this by 2 grains of quinine, with 5 of rhubarb, repeated three times daily during two days; treatment was thus continued four days, \bar{z} j. grs. 46 of quinine being taken in all, and the patient was discharged recovered in twenty-nine days.

Tertian Fever.—With reference to cases of tertian ague, I obtain the following information, namely:—In one case 2 grains of quinine were given three times a day during four days; 24 grains taken in all, and the patient discharged in eight days. In four cases quinine was administered in 3-grain doses, repeated three times a day. In one of these the treatment was continued four days; 36 grains were taken, and the patient was discharged in nine days. In two it was continued five days, the patient taking 45 grains; and of these one was discharged at the end of that time, the other being so in seven days. In one the treatment was continued six days; the patient discharged in fourteen. In one case, after this treatment had been continued seven days, it was modified, 2-grain doses being then given three times a day during six; this treatment extended over thirteen days; the patient took in all \bar{z} j. grs. 39, and was discharged in twenty-six days. In another case 3 grains of quinine, combined with 5 of blue pill, were given three times a day during two days, 2 grains of uncombined quinine being given three times a day during three more days; this treatment was continued five days; 36 grains of quinine given, and the patient at the end of the time discharged to duty. In one case 5-grain doses three times a day were continued during ten days, \bar{z} j. grs. 30 being taken in that time, and the patient discharged in eleven days. One was similarly treated during seven days, \bar{z} j. grs. 45 taken in that time, and he discharged in ten; and one during three days, he taking 45 grains, and being discharged in five. One patient had 5 grains of quinine, with 5 of rhubarb, three times a day during three days; took 45 grains, and was discharged in four days; and one who was treated with similar doses of quinine, with two grains of extract of hyoscyamus twice repeated, and then had a single 30-grain dose of quinine all in one day, 45 grains being thus taken, but no further treatment used, was discharged in eleven days.

Of two men who had 10-grain doses repeated three times a day, and afterwards by 3-grain doses similarly administered, one had the larger doses during four days, the smaller during two, or six in all; he took \bar{z} ij. grs. 18, and was discharged in sixteen. The other had the larger doses during two days, the smaller in five; took in all \bar{z} ij. grs. 55 in these seven days, and was discharged in twenty-seven.

One had two doses each of 10 grains, succeeded by 2 grains repeated twice a day during two days; thus he received medicine during three, took in all 28 grains, and was discharged in four; and one who, after one dose of 10 grains, received 5 grains four times in one day, and 2 grains three times a day during eight, was thus under actual treatment nine days, in which he took in all \bar{z} j. grs. 20; he was discharged to duty at the end of that time.

In one case \bar{z} j. of quinine was administered three times a day during two days; \bar{z} ij. were taken in all, and the patient discharged in thirteen days.

In one 30 grains were given, and repeated in the same day, after which 5 grains of quinine, with 5 of rhubarb, were given three times daily during three days; the patient was thus four days under treatment, took in all \bar{z} ij. grs. 15 of quinine, and was discharged in thirty-four days.

An analysis of these records will not, I fear, tend to increase confidence in the superiority of one method of administering this medicine over another. In conducting my investigations, every endeavour was made to observe similar conditions in the management of all cases which came under observation; various other plans of treatment were moreover observed, of which, although the particulars are unfortunately not now available, I am able to give the conclusions drawn from them at the time. In some cases no other treatment was employed than the exhibition of free purgatives, and keeping the patient several days on spoon diet; and young and robust soldiers so treated while labouring under a first, second, or even third attack of the disease, recovered quite as favourably and rapidly as others did who were treated by the remedies usually recommended. In old cases, however, and in those of patients

who were much debilitated, or who laboured under any of the complications of intermittent fever, more especially enlargement of the spleen and cachexy, treatment became a matter of serious difficulty. Quinine in such cases was the remedy most to be confided in, in some dose or other, and combined in the various ways that have been detailed.

But it often happened that, from no evident cause, some one of the usual remedies given as an anti-periodic would fail, and another succeed. Thus, on the occasions mentioned, the ordinary sulphate of quinine failed to check the accessions, but that what was called the amorphous solution speedily had the desired effect; while in others, where first one and then the other of these seemed to have no effect, the employment of arsenical solution, sulphate of biberine, sulphate or carbonate of zinc, were followed by favourable results.

It is useless to warn soldiers against the circumstances that induce intermittent fever. The occurrence of one attack after the committal of an irregularity does not teach them, as a rule, to avoid a similar. Medicine mostly seems to have a partial and uncertain remedial power so long as a person continues under the conditions that in the first instance induced the attack; and therefore the removal of the person to a less malarious district, whether that be in India itself or to England, becomes, in the cases of all who are confirmed subjects of ague, a matter of necessity.

(To be continued.)

ON AN EPIDEMIC VISITATION OF JAUNDICE.*

BY THOMAS HAYDEN, F.R.C.P., &c.,

Physician to the Mater Misericordiae Hospital.

IN the course of January and February of the current year several cases of jaundice, of a mild but decided character and brief duration, came under my notice in rapid succession. Many of these cases were under treatment at the same time, and I was struck with the similarity of symptoms and course which they all presented; but still more forcibly by the circumstance that the greater number of them had occurred in a single institution, and amongst persons circumstanced alike in regard to food, exercise, and surrounding temperature. I have been enabled to follow these cases to the conclusion, with one exception; and all, if that one be omitted, of the termination of which I have no knowledge, made a rapid and complete recovery.

Case 1.—In the second week of last January a gentleman, aged about forty-five, of studious, sedentary, and abstemious habits, who had been living rather sparingly, and upon unwholesome food for the preceding few weeks, called on me. He stated that, during the last week he had experienced great languor and total loss of appetite; the bowels were confined; the skin of a deep lemon tint; urine loaded with bile pigment; stools clay-coloured; pulse remarkably slow and weak; surface cool, and tongue slightly coated with a white fur, and moist.

Under a simple treatment with blue and compound colocyath pill, and nitro-hydrochloric acid in infusion of chiretta, he was restored to perfect health in the course of about ten days, a slight icteric tinting of the conjunctiva remaining a few days longer.

Case 2.—Mr. G., aged about twenty-five, a student residing in the same collegiate institution as the last mentioned patient, presented himself to me in the early part of January. The skin was of a deep lemon colour; urine loaded with bile; bowels confined; pulse slow; great languor, nausea, and tendency to fainting. For a few days previously he had been languid and listless, with loss of appetite, and confined bowels; he was then attacked with rather severe pain in the epigastrium, lasting a few hours, and subsequently became jaundiced.

* Read at the meeting of the Medical Society of the College of Physicians, Dublin, March, 1869.

After a week's treatment, similar to that mentioned in the preceding case, he became convalescent, and recovered his ordinary health in about three weeks from the date of his first illness; the jaundice slowly disappeared, and the urine resumed its natural appearance.

Case 3.—Mr. D., a student, and up to a few weeks previously, a resident of the same institution as the preceding patients, became jaundiced after a few days of *malaise*, about the 20th of January last. He attributes his illness to his having partaken of a bad beef-steak at a tavern about that time; he states that of late he has not had sufficient variety of food, having subsisted chiefly upon beef-steak, and this often of an inferior quality. Skin lemon-yellow; urine deeply coloured with bile; bowels confined, and stools "formed," small, and clay coloured; a general itching over the body, but most urgent in the conjunctivæ; there was likewise slight hepatic enlargement, with tenderness at the epigastrium. A few leeches were applied over the seat of tenderness, and subsequently warm poultices; treatment otherwise as in the preceding cases.

Feb. 5.—No abdominal tenderness; jaundice has nearly disappeared; urine coloured only at intervals; feels much better, and can take some food without repugnance. Pulse remarkably weak and slow.

Feb. 8.—No jaundice or bile in urine; bowels still confined; is still weak, but otherwise well. In the course of a few days more this gentleman was restored to his usual health.

Case 4.—Mr. R., a student in the same institution, and previously healthy, on Sunday January 17 felt "out of sorts," and in the course of the succeeding night was attacked in bed with severe pain in the epigastrium, which lasted about six hours, and caused him to writhe with suffering; there were at the same time constipation and loss of appetite, and the skin began to assume a jaundice tint. I saw him on the 24th of January. The pulse was then slow; the tongue slightly coated; skin and conjunctivæ of a deep lemon hue; urine deeply coloured with bile; there were languor and loss of appetite, but no pain.

To have blue pill and *co. colocynth*, of each gr. v.; and afterwards a seidlitz powder.

Jan. 25.—Bowels imperfectly moved; stools "formed" and pale; pulse 40, and weak; feels better, and can now take a little food; jaundice disappearing. To have nitro-hydrochloric acid with infusion of chiretta. About the 30th of January he left for the country, being still weak, but all other indications of illness having disappeared. He has since returned to Dublin, and is now in excellent health.

Case 5.—Mr. L., a student resident in the same institution, felt unwell on the 27th January, and in the course of that night had dull aching pain in the epigastrium; there were likewise nausea and repugnance to food. A week later he noticed an icteric tint of skin. I saw him on the 5th of February—*i.e.*, nine days from the date of his first illness; he was then jaundiced, both the skin and conjunctivæ being of a light lemon hue; urine deeply tinted with bile; pulse 60, soft and weak. There was tenderness on pressure in the right hypochondrium, and here the liver was felt projecting slightly below the costal cartilages; tongue slightly coated with a "milky" fur; bowels confined. To have two leeches to right hypochondrium, one-twelfth of a grain of resin of podophyllin, with two grains each of blue pill and compound aloetic pill, every fourth hour, till a free action of the bowels took place, and subsequently infusion of chiretta with nitro-hydrochloric acid thrice daily.

Feb. 8.—Is less jaundiced; bowels acting well; bile still in urine; pulse 84, weak; tongue less coated. Continue. In the course of three days subsequently this gentleman was quite well, and had lost all appearance of jaundice.

In addition to the foregoing cases, five in number, which came under my notice from a single institution within a period of a month, all strikingly similar in regard to history, symptoms, and progress, I saw on January 25 another case, that of a coachman, aged thirty-six, who had been

taken ill three weeks previously with pain in the epigastrium, languor, debility, occasional vomiting after meals, total loss of appetite, and constipation. When seen by me he was deeply jaundiced, the skin being of a lemon tint, and the urine coloured with bile. The treatment was the same as in the preceding cases; but as I have not had the advantage of seeing this patient a second time, and cannot, therefore, speak as to the duration of his illness, or the effect of treatment, I do not wish to adduce his case as an example of the mild and transient form of jaundice illustrated in the preceding cases.

I have learned that two other cases which I did not see, making seven in all, occurred in the same institution and at the same time as those which I treated. In these the symptoms were as nearly as possible identical, and similar to those exhibited in the cases above narrated; they both got well within a period of three weeks without any special treatment.

Case 6.—A gentleman aged twenty-six, accountant in a merchant's office, consulted me on the 12th March. His health was excellent up to Tuesday, March 2nd. On that day he took a bottle of porter in the afternoon, and immediately afterwards ran about two hundred yards to one of the railway termini, to meet a friend who was to arrive by train, and became heated. On the following day he felt unwell, was languid, drowsy, and had no appetite for food; there were likewise much flatulence and nausea, but no pain at the epigastrium or elsewhere. His skin was noticed by his friends to be slightly jaundiced, the tint becoming deeper from day to day, and on Saturday March 5th assuming a very decided character, and attracting his own attention. Urine of a deep porter colour; bowels confined, and evacuations clay-coloured; tongue clean; pulse 84 and weak; entire cutaneous and conjunctival surface of a deep lemon colour. No tenderness in the region of the liver or stomach; no enlargement or other alteration of the liver to be detected. To have nitro-hydrochloric acid in infusion of chiretta every fourth hour, and twice daily a pill composed of extract of hyoseyamus gr. i., with gr. ij. each of blue and *co. colocynth* pill.

I have since seen this gentleman on two occasions, for the last time on Monday, the 22nd March. He had then lost all appearance of jaundice with the exception of slight colouring of the conjunctivæ; the urine had resumed its natural appearance; the bowels acted regularly, and the stools were bilious; pulse 96, but weak. He had, in short, recovered his usual health, save as regards loss of strength consequent upon protracted inability to take food.

In all the preceding cases the earliest symptoms were those of derangement of the stomach, flatulence, and epigastric distension, amounting in the majority to severe pain of a paroxysmal character, and lasting several hours.

Closely following these symptoms were well-marked jaundice of a lemon tint, the presence of bile in the urine, constipation of the bowels, and loss of colour in the stools.

There were the usual premonitory symptoms of languor, nausea, and repugnance to food; and after the appearance of jaundice, falling of the pulse and temperature—the former in one instance to 40 in the minute.

In the greater number of the cases the liver underwent a decided increase of volume, and was tender to pressure; both these symptoms being promptly alleviated by the application of a few leeches and warm poultices to the epigastrium, and in the course of a few days entirely removed under the simple treatment already indicated.

The average duration of illness in the six cases was seventeen days; the treatment was nearly alike in all, and the progress to recovery uninterrupted.

Those who came directly under my notice were all males of adult age. I saw casually, however, in the course of the present month, an old man similarly affected, whose history led me to conclude that his case belonged to the same category as the preceding.

These cases were all free from fever; there was no enlargement of the spleen; no cerebral disturbance; and the

progress to recovery was uninterrupted by complication of any kind.

There can be no doubt as to the character and immediate cause of the jaundice; it was of the simple catarrhal form, and consequently upon temporary derangement of the alimentary canal. But as to what the cause of this derangement was, which operated almost simultaneously upon so many inmates of the same establishment, my inquiries have hitherto led to no satisfactory conclusion.

The patients had been all well fed, the water drunk by them was obtained from a pump which is at a considerable distance from all sewers and other sources of contamination, and is clear and pleasant to drink; it has been, moreover, used for the last fifteen years in the same institution, and is now being freely drunk by several residents in it who have not been affected, and yet, up to January of the current year no case of jaundice appeared in the establishment.

Can the recent high temperature, almost unprecedented for the season, have had any share in the causation of jaundice in these cases? If so, similar cases must have come under the notice of other members of the Society at the same time, and the visitation should be regarded as a veritable epidemic. Or must an explanation be sought in the operation of some special agency, dietetic or hygienic, within the walls of the institution itself?

I regret I cannot give a satisfactory answer to either of these queries, but I incline to the opinion that the cause was atmospheric, as cases of mild jaundice have been, in the experience of other physicians as far as I can learn, more than usually frequent within the last two months.

Under the impression that some assistance towards a solution of this problem might be obtained from a comparison of the weekly and daily temperature during the months of January and February of the preceding and of the present year, I have had the accompanying table* made out from the weekly returns of the General Registry Office.

A scrutiny of this table shows that, whilst the *weekly* temperature, maximum, minimum, and mean, of January and February 1869, was on the whole considerably in excess of that of the corresponding period of 1868, the *daily* range of temperature in these two periods was nearly the same.

The high temperature of January and February last, if at all contributory in the causation of this epidemic, must have been so by its absolute or its relative excess. If simply by its absolute excess, then we should have had a still more general and severe visitation of jaundice in the autumn of last year, when the temperature was exceptionally high; but nothing of the kind, so far as I am aware, occurred at that time. If, on the other hand, the diurnal variations of temperature during the first two months of the current year were competent to produce this remarkable effect, we should, in that case, have witnessed a similar phenomenon at the commencement of the preceding year; but jaundice was not then remarkably prevalent.

I believe, therefore, I am warranted in concluding that the theory of simple thermal causation cannot be maintained.

But atmospheric heat as a factor, in conjunction with other causes, is not thereby excluded, much less atmospheric agency in the general sense.

The subtle influence, chemical and physical, of the atmosphere as such, and of its incessant fluctuations in regard to quality, pressure, &c., upon the constitution and circulation of the blood, must be much more precisely determined than is possible with our present knowledge, before we can venture to affirm that it has no share in the production of an epidemic of this, or indeed of any other character.

Murchison, in his recent work,† states that, "inasmuch

as catarrh of the stomach and duodenum appears sometimes to be induced by a chill, or other atmospheric influence, jaundice from catarrh of the bile-ducts occasionally prevails as an epidemic."

In the *Medical Times and Gazette* of June 8, 1861,* I find the following extract from *Recueil de Mémoires de Médecine Militaire*, and headed "An Epidemic of Jaundice in Italy":—

"M. Martin gives an account of an epidemic of essential jaundice which he had the opportunity of observing among the artillery and engineers of the French army stationed at Pavia during the Italian war. It commenced during the great heats of August, and terminated by the end of October. There occurred 71 cases in an effective of 1,022 men. The causes he considers to have been the unusual heat, which gave rise to great congestion of the liver; the fatigue of long marches (the mounted men suffering oftener in proportion than the unmounted), indulgence in alcoholic drinks, and marsh miasmata. Great increase in the size of the liver in most of the cases, and of the spleen in many, was observed, and all complained of pain in the epigastrium and in the hypochondria; in fact, this last was the first symptom of the approaching jaundice. None of the cases proved fatal. Professor San-Galli informed the author that a similar epidemic prevailed in the town of Pavia at the same time."

Frerichs,‡ speaking of epidemic jaundice, says:—"The epidemic in Chasselay, which was observed by Chardon, was very mild. The jaundice commenced with gastric catarrh, and was unaccompanied by fever; the stools were in all cases pale. Not a single case proved fatal. It was to all appearance an example of simple catarrhal jaundice." He adds:—"The anatomical cause of the jaundice in the epidemics just mentioned is very imperfectly known, and hence the determination of the mode of production of this symptom must in many respects remain uncertain."

The applicability of the preceding quotations to the subject of this paper will be sufficiently manifest to the Society.

A WORM DISCHARGED THROUGH AN ABSCESS.

By FRANCIS McEVoy, L.K.Q.C.P., L.M., M.R.C.S.
Eng., &c., Balbriggan.

A BOY aged fourteen years, delicate from birth, pale, thin, and small for his age, had passed at various times a vast quantity of worms, both by stool and mouth; had a very severe cough, and spat blood twice or thrice. His poor mother, who has since died of cancer of stomach, at my solicitation sought further advice, and consulted several doctors both in town and country, and also brought him to hospitals without the least alleviation of his symptoms. His complaint was phthisis.

One day she called and brought me a red ticket, and requested that I would see him, as he had a lump like a blind boil just over his stomach. I did so, and found it as she stated. As I could not say what it was, I told her to wait, watch, and poultice, as I thought it would probably gather and break, and that I would call occasionally to see him. She did so, and in about three weeks I was again requested to see him in haste, although I had seen him the previous day, when he appeared to be going on very satisfactorily.

His mother informed me that upon removing the poultice in the morning to put on a fresh one, she perceived a white point sticking out of the middle of the abscess. At first she considered it to be matter, but on closer inspection she could see it move. She put on the same poultice again, and sent for me. Upon removing the poultice I perceived about two inches of one of the Lumbrici protruded.

† Lectures on Diseases of the Liver. 1865. Page 133.

ding from the abscess. I seized it, and gently drew forth a large worm, nine inches long. It appeared to have been coiled up underneath the skin, and must have escaped through some ulceration of the intestines or stomach.

There was not much matter in the abscess, if abscess it could be called; it healed up in a few days, and the boy recovered from it, but in about three months succumbed to the original disease. There was no *post-mortem* permitted.

This gives a mean ratio of 7·8 per 1,000 of mean force in the Army, against 8·1 in the Navy for the whole four years.

The consideration of the circumstances which are most likely to affect the organs of circulation in the soldier and sailor embraces a consideration of the life that is led in both Services, and might be spun out to an almost indefinite extent; I shall therefore mention what seem to me to be the striking features only as shortly as possible.

Those who enter the naval service comprise two great classes; first, those who join during the age of boyhood and grow up in the service; and, secondly, those who join at a later period, a class made up of a most heterogeneous mixture, who seldom become good seamen unless previously accustomed to the water, and are generally, after a short residence on board, turned into cooks' mates, tailors, or any employment which they may have been brought up to, and which is required on board.

Returning to the first class; the sailor boy, entering as he does at the age of fourteen, begins the rough and active life he is to pursue at the age of boyhood, the age of somersaults and scampering, when everything is done at a trot, and when active exercise is not only a pleasure, but also a necessity; clad in a loose flannel undershirt, a loose serge or white shirt fastened only at the wrists and open at the throat, a pair of trousers tight only at the hips, a soft cloth cap which serves for a pocket as well as a covering, and without shoes, the sailor must be allowed to be free in all his limbs, free from pressure on any vital organ, and admirably clad for active exercise; in performing the duties of his profession he only continues the exercises and incessant movements of boyhood in a more regulated manner; fed regularly and well, and unable to indulge any craving for alcoholic fluids or tobacco, except on rare occasions; his muscular system, strengthened by constant exercise, becomes well developed, and the restless boy shoots up into the hardy and athletic seaman. Many, however, break down during this course of training; and when it is considered that almost hourly the sailor is called on for exertions which try his strength to the uttermost, it is only what might be expected, that those who suffer from any organic debility should soon sustain injury. As he advances in years, he is exposed to influences, and is allowed privileges, that affect his constitution more or less after a certain time; first of these influences is the debilitating effect of a long residence in a hot climate, combined with broken rest and exposure during sleep to the hot and close air of a cockpit, this, along with a salt meat diet, brings down the flesh and strength rapidly; and I can recollect at least one instance in which these influences alone produced very severe functional derangement of the heart, which passed off rapidly when the patient was sent to a cooler climate, and got a fresh meat diet. Next to this in its deleterious effect comes the effect of certain diseases where there is a tendency to involve every part of the system, such as rheumatism and syphilis; both of these diseases are extremely prevalent in the naval service, the first from the vicissitudes of temperature and the constant habit of washing decks; the latter, perhaps, to a less extent than in the army; and I need not allude to its causes. With rheumatism in every class, whether sailor, soldier, or civilian, cardiac complications are not uncommon. With regard to syphilis, on the other hand, although I do not believe that aneurism can occur without some previous organic change which impairs the elasticity of the vessel, and Dr. Davidson, of Netley Hospital, has given a most interesting series of cases in the Blue Book of 1862, showing how the syphilitic poison may produce changes in the arterial coats; it is probable that the amount of arterial disease arising from it is almost infinitesimal, however much it may conduce to cardiac affections.

After the age of eighteen the sailor is allowed to use any quantity of tobacco he likes, and nearly everyone avails himself of the privilege, more especially as the very strongest and finest tobacco leaf is provided for their use; so strong is it, that I have seen few but seamen who could

ON DISEASES OF THE HEART AND ANEURISM IN THE ROYAL NAVY AND ARMY.*

By G. ROBERTSON, M.D., ROYAL MARINE ARTILLERY.

INTIMATELY connected as morbus cordis and aneurism are in many of their features, it is scarcely possible to treat of the causes of one without alluding to the other; I intend, therefore, although I have not met with any cases of aneurism during my service afloat, to begin by comparing the mortality from this disease in the Army and Navy, as it is given in the Blue Books during a period of four years; then, the mortality from cardiac affections; and lastly, to mention some of the influences which seem to me to be most likely to affect the prevalence of these diseases.

ARMY.

Year.	No. of cases.	Strength.	Ratio per 1,000 of mean force.
1863	60	183,747	·32
1864	82	182,048	·45
1865	68	174,847	·39
1866	80	166,142	·48

NAVY.

Year.	No. of cases.	Strength.	Ratio per 1,000 of mean force.
1863	2	54,090	·03
1864	10	53,000	·18
1865	5	51,210	·09
1866	6	49,475	·12

This gives a mean ratio of mortality of ·40 in the Army, and ·12 in the Navy per 1,000 of mean force for the whole period.

The mortality from cardiac affections during the same period was as follows, viz. :—

ARMY.

Year.	No. of cases.	Strength.	Ratio per 1,000 of mean force.
1863	120	183,747	·65
1864	120	182,048	·65
1865	127	174,847	·72
1866	150	166,142	·90

NAVY.

Year.	No of cases.	Strength.	Ratio per 1,000 of mean force.
1863	27	54,090	·49
1864	36	53,000	·67
1865	24	51,210	·46
1866	26	49,475	·52

This gives a mean ratio of mortality of ·73 in the Army, and ·54 in the Navy per 1,000 of mean force for the whole period.

From this it will be seen that the mortality from both diseases is not only considerably in excess of that of the Navy in the Army, but is also on an increasing scale, whilst in the service afloat it may be considered to be stationary; on the other hand, it is a singular fact that the number of admissions for cardiac affections in the Navy is in excess of that of the Army, the numbers being as follows :—

ARMY.			NAVY.	
Year.	No. of cases.	Ratio.	No of cases.	Ratio.
1863	1368	7·4	464	8·5
1864	1390	7·6	462	8·0
1865	1405	8·0	433	8·5
1866	1390	8·1	327	6·7

* Read before the Army Medical-Chirurgical Society of Portsmouth, 2nd June, 1869.

smoke or chew it unmixed, and yet nearly every sailor, more as a part of his profession I believe, carries a quid in his mouth morning, noon, and night, and frequently swallows the juice. This I consider to be the principal cause of the number of admissions for cardiac affections being in excess in the Navy (and I can recollect several instances, both ashore and afloat, where the use of tobacco was followed by palpitation, tumultuous action of the heart, and a most alarming conglomeration of bruits).*

With regard to the second class, many of whom become stokers, it is worthy of notice that out of thirty-five cases of aneurism admitted on the sick list during the period for which I have given the mortality, no less than seven cases occurred among stokers, although they do not number more than one in twenty in the service; this particular class, frequently enjoying considerable periods of rest, are called on for the severest exertions when the ship is under steam, and are exposed at the same time to a temperature of 120° and upwards. In a tropical climate it is no uncommon thing to see a stoker at such a time hauled up from the stoke-hole in a state of partial or complete syncope, and so little do the men themselves think of it, that they seldom take the trouble to call the medical officer, returning to their duty when they have recovered their senses. As might be expected, this class suffer severely, especially from valvular disease.

The soldier, on the other hand, entering upon his career at the age of eighteen at the earliest, and twenty-one on the average, has almost invariably learned a trade or earned a livelihood by following some form of manual or mental labour, which, whether it be that of the plough-boy, tailor, clerk, or shoemaker, has in all probability been followed sufficiently long to mark its characteristics on his frame, in the flat chest, the stooping spine, the round shoulders, and head thrown well forward; at the same time it is not improbable that want has been faced and felt at one time or another, at the period when the boy, stepping into manhood, with his functions at their greatest activity, requires that ample and wholesome nourishment which conduces to the foundation of a sound constitution and good muscular development. In many instances, after following a sedentary employment for a series of years, the recruit is called on to task his unexercised physical powers by (what is to him) constant and violent exercise. Every man that joins the service must have a seemingly sufficient muscular development, but although perfectly healthy to all appearance at the time of enlistment, it is utterly impossible to judge of what the effects of a totally different life may be. Accustomed to an easy, perhaps *negligé* fit, the recruit is henceforth carefully buttoned up to the chin, in a coat or jacket fitting like a glove round his neck and chest, then handed over to the tender mercies of a drill sergeant, who sets to work in nearly every instance to alter every habit in the way of standing, walking, and running to which the patient—I can call him no other name—has been accustomed; his head is thrown up, his shoulders thrown back, and his chest thrown out. This of itself seems unlikely to do harm at first sight; but look at it physiologically, and what do you find? Why, that the combination of these requirements renders it absolutely necessary that a certain amount of air should be retained in the chest to give it the requisite development, and afford the muscles of the chest a fixed point on which to act; the blood, therefore, does not pass so freely through the lungs, and the right cavities of the heart become gorged; this necessitates increased exertions on the part of the organ to carry out its functions; and the result is—if the organs do not rapidly accommodate themselves, as they do in most cases, to the alteration in the shape of their dwelling—the first step towards permanent dilatation, hypertrophy, and valvular disease. In addition, to exercise his hitherto un-

exercised limbs and lungs, he is made to run as if he were training for a pedestrian—an individual, by the way, who would no more think of running with his neck and chest tied up than of flying. It is a fact worthy of notice, in connection with the introduction of the running drill, that in the Royal Marine Artillery, the number of admissions for the two years previous to the introduction of the running drill, of men suffering from cardiac disease was 24 in 1865 and 26 in 1866; in the summer of 1867 the running drill was introduced, and the admissions the year after its introduction amounted to 47 in an average force of 1,750 men; and the admissions during the first quarter of this year have amounted to no less than 25—a most remarkable increase, which can be accounted for in no other way. This drill is only practised during the winter months by the Marine Artillery, and despite the heavy drills they have to undergo during summer, I have observed that the number of admissions since bear no proportion to the number during the winter months. Out of these 25 cases, 20 have been invalidated from Haslar Hospital, and not one has returned to duty. In addition, one death from aneurism has occurred during the same period, and two cases of the same disease have been sent to Haslar Hospital. Another item in connection with the soldier's accoutrements tells most severely against his chance of escaping heart disease, and that is the knapsack. Whole volumes have been written to point out its baneful effects; I shall therefore content myself with saying that it is not the principal cause, but an additional circumstance which, in combination with other causes, tends to prevent the easy play of the lungs, and forces the heart into a state of unnatural activity. The yoke pattern knapsack is a great improvement, but I think it would be a greater improvement still if they could be dispensed with altogether; and really if it is true, as some great commander said, that battles are won more by the legs than by the arms, our chance against any great power whose troops are clothed more in accordance with what is required for them in the way of rapid movements, ought to be a poor one, the only advantage on our side being that our men could not possibly run away, and would have to fight the harder.

In addition to the effects of climate, disease, and tobacco, another influence may be considered to affect the soldier to a serious degree, and that is, the effects of diet; in the Navy each man is allowed a pound of fresh meat, and a pound and a quarter of biscuit, which is quite equivalent to a pound and a half of soft bread; in the Army, on the other hand, only three quarters of a pound of meat and one pound of bread is allowed, in addition to vegetables; the meat, when freed from bone, rarely amounts to more than eight oz., which is scarcely sufficient for one meal; this meal the soldier takes about one o'clock in the day, about four or five o'clock he has tea, and nothing else afterwards. Now it must be remembered that in a healthy man four hours are amply sufficient to digest a meal; therefore, about eight o'clock the soldier's stomach is empty, and by nine o'clock he is probably very hungry, he cannot get anything cooked, and seldom cares for dry bread, so he goes to the canteen or the dram shop, and drinks one or two or even more glasses of beer or spirits on an empty stomach; this allays the craving for food, but the result is that the man's system has imbibed a very considerable quantity of alcohol, a substance well known to produce fatty degeneration of almost every tissue; in aneurism, we find that atheromatous deposits are almost constantly present in the coats of the arteries, which I am sure may in many instances be ascribed to the effects of alcohol. Now take an instance, a man who is a dram drinker and whose system is degenerating, is called on for some sudden or violent exertion, which forces the blood more rapidly and strongly through the weakened arteries; if no one part of the artery is weaker than another, the impaired elasticity of the vessel cannot overcome the pressure, and the result is a general dilatation of the artery. If, on the other hand, one part is weaker than the rest of the vessel, the constant dashing of the blood against it forces it out, and a circum-

* Since writing these remarks I have been informed by Mr. Grose that, about thirty years ago, H.M.S. *Bellerophon* was disabled in Plymouth Sound from the number of cases of cardiac affections occurring on board. Plymouth Hospital was filled, and the cause of the extraordinary number of cases was only found out by the confession of one of the men who was dying.

scribed or diffused aneurism is found, according to the extent to which the coats give way.

In morbus cordis the same cause produces fatty degeneration, and allows the valves to become ruptured, and in delirium tremens or dyspepsia *é potu* I think you will all acknowledge that no complaint next to want of sleep is made by the patient so frequently as that of pain in the side, beating and palpitation of the heart.

Lastly, my ideas are, that it would be for the benefit of the Naval service if the use of tobacco was checked, or the leaf mixed with some innocuous substance before being served out to the men; with regard to the soldier, that drill is begun where it ought to end, namely, under the drill instructor instead of the gymnasium; in fact, that the recruit should be gradually trained in the use of his muscles by men acquainted with muscular anatomy, who would know what muscles to exercise, in order to acquire a graceful and easy carriage before sending the man to the drill instructor; secondly, that the collar and fastening round the chest should be done away with, and lastly, that a light meal should be allowed about eight o'clock p.m.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.,

COOMBE LYING-IN HOSPITAL.

SOME CASES OCCURRING IN THE PRACTICE OF DR. KIDD.

Uterine hæmorrhage for twelve months, dependent on fibrous polypus of uterus—removal by écraseur.

MARY C., *æt.* fifty, a widow whose husband had been dead for fifteen years, was admitted into the Coombe Lying-in Hospital, May 31st, 1869. She had been a wife for twenty-six years, and was the mother of three children. She had menstruated very irregularly up to the previous June; hæmorrhage from the uterus then commenced, and lasted until August, when, having been treated at a country dispensary for the discharge, it ceased for about three months, at the end of which period it recurred, and continued with increasing severity up to the time of her reception into hospital.

Examination revealed the presence of what proved to be a fibrous polypus of the uterus, about two and a half inches long, and one inch and a half in diameter, attached to the fundus by a pedicle, by means of which it was suspended in the vagina, hanging through the os externum.

On the 1st of June, chloroform having been administered, it was removed by Dr. Kidd in the following manner:—The tumour having been exposed by a duck-bill speculum, was seized by means of a vulsellum, and drawn down as far as possible; a loop of soft iron wire attached to an écraseur was next passed over the vulsellum and around the pedicle of the polypus, which was then gradually divided. The woman made a rapid recovery, was entirely freed from her troublesome symptoms, and on June 14th was sufficiently well to be sent home.

In his remarks to the class upon this and similar cases, Dr. Kidd dwelt upon the necessity of always making an examination in cases of continued disturbance of the uterine functions. Where persistent and uncontrollable bleeding is found in a non-pregnant woman, and where, upon sounding the uterus, we find it increased in size, or where, examining by the bi-manual method of Marion Sims, we discover the womb to be enlarged, we are justified in suspecting the existence of a polypus, although the only certain proof of its presence is its detection by the eye or finger. In this instance the nature of the disease was readily discovered, as the polypus could be easily felt and seen in the vagina; but in other cases, more elaborate means of exposure were necessary.

Literature.

DIABETES.

WE are rather late in drawing the attention of our readers to a second edition of Dr. Pavy's most valuable work on Diabetes.* For two years this standard medical treatise has been out of print. Six years have elapsed since the author expounded to the profession his original views on "Glycogenesis," in the first edition of this work. These views have been, as was to be expected, freely criticised: some have regarded them as erroneous, whilst others have only accepted them to a limited extent; but still, all are agreed on this, that the views of Dr. Pavy on a most difficult subject are extremely original, and well deserving the careful attention of the scientific physician—and that careful attention they have certainly received.

In the preface Dr. Pavy informs us that his subsequent experience has only served to confirm the accuracy of the views he advocated six years ago, and, moreover, that the experiments of other physiologists, both English and Continental, have also tended in the same direction. This says a great deal; for whether we agree or not with Dr. Pavy's views, it must be always satisfactory to read of the experiments of one who seems so pre-eminently truthful in all the minute details of the experiments he records. Dr. Pavy deals in the first part of his book with the various tests of the presence of sugar, and the means for calculating the amount present in the urine. Many good practical hints are given. The physiology and pathology of the disease are then fully discoursed upon. We strongly recommend medical men to read Dr. Pavy's experience respecting the treatment he proposes for this formidable disease, which has baffled, and we fear we must add, in most cases, still does baffle, our best and most painstaking endeavours to effect a radical cure.

SUBCUTANEOUS CONDYLOMA

ACCORDING to Dr. Teisse, the so-called subcutaneous condylo-ma is a monstrous hypertrophy of the cellular portion of the follicle.

PRUSSIC ACID.

WE learn from the *Journal des Connaissances Médicales* that at the last sitting of the French Academy of Medicine, Dr. Scouttetenn communicated the substance of an essay which created quite a sensation. It was a posthumous disquisition on hydrocyanic acid, found among the papers of the late celebrated Professor Schoenbein of Baden. The question discussed was, whether there was a test for the above-mentioned liquid besides those of M. Liebig and M. Buignet, which, within certain limits, may reveal the presence of prussic acid, but are insufficient to fix its quantity and detect a crime with certainty. Professor Schoenbein then proceeds to describe a reagent discovered by himself, and delicate enough to bring out to view even the millionth part of a drop, whether diluted with water, or vaporised in the air: a circumstance affording a new proof of the incalculable divisibility of matter. Dr. Scouttetenn, who lives at Metz, announced in his communication that he had repeated the late Professor Schoenbein's experiments with the aid of two chemists, MM. Guébin and Pont, and that he begged to submit some of the test-paper prepared by himself to the Academy for further trial. The specimen forwarded was of the kind called filtering paper, and had been soaked in a solution of three gms. of gualacum resin in 100 gms. of alcohol. To use it, a solution of ten decigr. of sulphate of copper in fifty gms. of distilled water should be made, and the paper, which is white, cut into narrow slips. One of the latter being wetted with the solution, it is then exposed to the action of the minute quantity of hydrocyanic acid dissolved in water and suspended in the air; the paper will then instantly turn blue. Dr. Scouttetenn remarks that these slips of paper will be useful in examining the quality of the medicinal waters or syrups containing a very small quantity of the acid. The paper need only be placed on the unstopped neck of the phial containing the medicine, and the blue colour will at once become visible. Various other experiments are described, all tending to the same result.

WEDNESDAY, JULY 7, 1869.

FEMALE PHYSICIANS.

THIS subject has so often been noticed in our columns that our readers will probably be interested to learn that there is some prospect of the Edinburgh University opening classes for ladies.

The following remarks appeared last week in the *Scotsman*, a powerful daily newspaper, often called the *Times of Scotland* :—

“Three months ago, we noticed the facts that Miss Garrett (who had in vain sought medical education in Edinburgh in 1862) was passing brilliant examinations for the degree of M.D. in the University of Paris, and that at the same moment another lady had come to request from our University the opportunity of fitting herself for the medical profession. We anticipated that liberal feeling in this matter had so far advanced, that what was refused in 1862 might be granted in 1869; and so the event proved: large majorities both in the Medical Faculty and Senatus voted that Miss Jex-Blake should be admitted to the summer classes at least as a tentative measure. But the outcry was revived against the impropriety of “mixed classes,” and it was ostensibly on this ground alone that the University Court, “considering the difficulties at present standing in the way,” refused its sanction to the proposed measure.

“In the meantime, other ladies, hearing that there was a chance that they might at last be able to obtain at Edinburgh the education they had vainly sought elsewhere, have come forward; and last Friday a second petition was presented to the Senatus Academicus, praying that its members would recommend the University Court to sanction the matriculation of women as medical students and their admission to the usual examinations, on the understanding that separate classes should be formed for their instruction. This narrows the whole question to a single issue. The propriety of joint medical study by men and women, and the difficulties that might or might not attend it, are not now elements in the case;

the ladies accept the fiat of exclusion from the public classes, but they think that the very fact of that exclusion gives them a right to ask that other arrangements shall be made on their behalf, that the sanction of the University shall not be refused if, by arrangement with the Medical Professors, they are able to secure opportunities of adequate instruction. And when we learn that three ladies are now studying in the Medical School of Paris, two at Vienna, and eight at Zurich, while one woman has recently taken the degree of M.D. even at St. Petersburg, it does not seem that English and Scotch women are very unreasonable in urging their present modest request. Will it be for the credit of this country if, after repeated applications at one place of education after another, our countrywomen are driven abroad to seek the instruction which they are bent on acquiring, but which is churlishly denied to them in their own land?

“It will, indeed, be hard for the University authorities to refuse this request without committing themselves to the policy of condemning women to compulsory ignorance whenever their desire for knowledge happens to rise above the ordinary dead level, of which we hear such frequent complaints. It is not a question now whether women shall be educated in medicine along with men, but whether they shall be educated *at all*, for to refuse such a request as this is practically to shut the door of knowledge in this country in the faces of one-half of its inhabitants. Society in general is interested in the question whether women are to be forcibly excluded from a profession where they claim to have a distinct place, and where certainly their services seem likely to be welcomed by many of their own sex—to whom only they have ever proposed to minister. Such exclusion is denounced as unworthy even of a Trades-Union, and why then should not opportunities of medical education be thrown open to women? It seems unlikely that Universities can fail much longer to recognise that the providing such instruction forms part of the duty imposed on them by the national trust they hold. The question is merely one of time, for the final issue can hardly be considered doubtful; but what has now to be decided is simply whether the University of Edinburgh shall lead the way in this important matter, or whether it shall relinquish the post of honour to some other University, by passing now a vote of exclusion which it may have to rescind in a very few years. As our University has always derived a large part of its repute from the excellence of its medical school, there seems an additional obligation laid on it to meet this new demand for medical instruction in a liberal spirit. And we understand that the ladies now knocking at their gates offer very liberal terms to have them opened. They fully recognise the unfairness of asking a professor to lecture to a class of one or two female students at a sacrifice of his time and labour; and they are consequently prepared to guarantee any minimum amount of fees which the Medical Faculty itself chooses to name. They thus seem really to leave the authorities no excuse—either on principle or on pecuniary grounds—for refusal.”

Notes on Current Topics.

Mortality in Hungary.

THE Hungarian bills of mortality do not give a favourable idea of the sanitary condition of that country. The *Neue Freie Presse* observes on this subject :—“Of 100,000 inhabitants 2,200 die annually in England, 2,380 in France, 2,220 in Belgium, 2,900 in Prussia, 4,500 in the Austrian monarchy, and in all Hungary 4,540; but in Siebenbürgen the number is only 3,097, and in the German part of the Banate 4,200, so that in the Magyar part of the country

the proportion is 5,240, or about two and a half times as great as in England. The high rate of mortality among the male population is not less surprising. While in the entire Austrian monarchy 10,570 males die for every 10,000 females, the proportion in Hungary is 10,658 males and in the Magyar parts of the country the average is so high as 10,700." The Austrian journal believes that with a little attention to hygiene Hungary might easily support three times as many inhabitants as England, whereas, in consequence of apathy and ignorance, the population is not near half so numerous as that of Great Britain.

The Dublin Hospitals.

THE eleventh report of the Board of Superintendence of Dublin Hospitals has been presented to Parliament. The hospitals included in the report are:—Westmoreland, Steevens', Meath Hospital, and County Dublin Infirmary, Cork-street Fever Hospital, House of Industry Hospital, Rotundo, Coombe, Hospital for Incurables, and Saint Mark's Ophthalmic Hospital. All the institutions were in a satisfactory state when inspected. We learn from a table appended to the report that the total number admitted to all the hospitals during the year was 10,229, which, with 831 who were inmates at the commencement of the year, makes a total of 11,060. Of these, 9,697 were discharged during the year, 505 died, 856 remained in hospital at the close of the year. The number of patients received during the year at the various hospitals was as follows:—Westmoreland, 594; Steevens', 1,932; Meath, 1,107; Cork-street Fever, 1,098; Hardwicke, 931; Whitworth, 996; Richmond, 1,204; Rotundo, 1,468; Coombe, 580; Incurables, 44; St. Mark's, 272.

The Medical Club Dinner.

At the last dinner Dr. Brady, M.P., presided. Sir J. Gray, M.P., Dr. Brewer, M.P., Dr. Lush, M.P., and Dr. Playfair, M.P., were also present, as were some members of the General Medical Council and some of the leading members of the Club.

"The Queen" and "The Club" were proposed by the chairman and duly honoured. Dr. Brady spoke confidently of the hopes of medical reformers, and referred to the success of the Superannuation Bill. Dr. Playfair also spoke on the same subject. Dr. J. G. Wakley, in reply to some observations of the chairman, thanked him and the meeting for the recognition of the labours of his late father in the field of medical reform.

Dr. Prosser James proposed the House of Commons, coupled with the name of Sir J. Gray, who, he could testify, was ever ready to serve medical men, and but for whom he believed the Superannuation Bill would never have been read a second time. The toast having been drunk with enthusiasm, Sir John Gray replied in the speech of the evening, telling most humorously his personal experience of Examining Boards.

The health of Dr. Lory Marsh was next proposed, and responded to by the amiable and talented originator of the Club in a suitable speech.

The First Political Act of the Medical Club.

THE battle of the sites for the new Law Courts having brought up incidentally the question of which would be

the better site in a sanitary point of view, the Medical Club organized a deputation to the Chancellor of the Exchequer, which was received on Thursday last, and pronounced in favour of the Embankment site.

The deputation was introduced by Dr. Brady, M.P., and very courteously received. Dr. Lory Marsh submitted to Mr. Lowe the reasons which medical men would urge on the question in a speech thoroughly to the purpose. Dr. Richardson enforced the views expressed by Dr. Lory Marsh, and Dr. Brady added a few words on the question. Mr. Lowe invited such members of the Club as were most interested in the matter to tender evidence to the Committee on the question, and, this having been accepted, the deputation withdrew.

The "Lancet" Again.

OUR recent exposure of the unfairness of a contemporary in its attack upon Dr. Fuller for advertising in the *Times*, while it continued its own most sensational announcements in that newspaper, has brought us so many expressions of gratitude from the heads of the profession, so many kind assurances that our independence is appreciated, and so many urgent wishes that we shall not abate our criticisms, that we looked again with some curiosity at the *Times* to see if the "*see Lancet*" again appeared. Right has prevailed so far as to drop that expression; but the *Lancet* has again returned to the plan of placing authors' names before their works, which it so fiercely denounced. Surely it ought to withdraw what it said on that head, or change its own plan. Those who are guided by its views may also be surprised to learn that it required fourteen separate advertisements to get rid of the last number of the paper that sees so distinctly the impropriety of "trumpeting." Here are the fourteen last flourishes of the *Lancet's* trumpet:—

THE LANCET.—Commencement of a New Volume, this day (Saturday), July 3rd. Half yearly subscription, 17s. 4d. stamped; unstamped, 7d. weekly. Order of any bookseller or news-vendor. Office, 423, Strand.

THE LANCET of this day (Saturday), July 3, contains:—

DR. HYDE SALTER on DISEASES of the CHEST.

MR. C. BROOKE on the Force of the HEART.

DR. R. JACKSON on SPINAL APOPLEXY.

DR. F. FUSSELL on ABDOMINAL TUMOUR.

DR. J. D. MOORE on a CASE of DEATH from A PISTOL SHOT.

DR. B. DUFFY on a CASE of EMPROSTHOTOSIS.

SURGEON-MAJOR WYATT on the DRY-EARTH SYSTEM.

THE ELECTION of COUNCILLORS at the ROYAL COLLEGE OF SURGEONS.

THE HARVEIAN ORATION at the ROYAL COLLEGE OF PHYSICIANS.

THE ANNUAL MEETING of the GENERAL MEDICAL COUNCIL.

A MIRROR of the PRACTICE of MEDICINE and SURGERY in the LONDON HOSPITALS, Reviews of New Books, Leading Articles, Medical Annotations, Special Articles, Correspondence, and News.

TERMS of SUBSCRIPTION, 17s. 4d. Half-Yearly, stamped. Office, 423, Strand.

THE *Pioneer* mentions a very serious accident which occurred to Dr. Dillon, Garrison Surgeon of Allahabad. The accident is said to have occurred in this way:—On

Tuesday morning Dr. Dillon was going out for a ride. His horse, a rather restive animal, began to jump and prance before he was fairly in the saddle, and threw him to the ground. The doctor fell on the back of his head with much force. He has been insensible ever since (adds our contemporary), and is still, we regret to say, in a precarious state.

Health of Harrogate.

REPORTS are, we learn, in circulation in various parts of England, especially in our own and more northern counties, that a malignant fever has been raging in Harrogate, and people dying with rapidity. The *Harrogate Herald* avers that they are wholly untrue. Harrogate, one of the most healthy spots in England, never showed so low a death rate as it does at the present hour. Within the last two months there have been cases of scarlatina among children; but, so far as we can ascertain, not one adult has been attacked by it. The deaths registered from the 1st of May to the 21st of June, in the years 1867-8-9, give the following results:—In 1867, 30 deaths; in 1868, 25; and in 1869, 27. This gives an average of $27\frac{2}{3}$ deaths in each of the periods named; and shows that the actual mortality of the present year has been below the average. The whole of the deaths from fever in these returns are those of three children. The population of the sub-district is fully 10,000. Hence, as these official returns show, the mortality is considerably less than $1\frac{2}{3}$ per cent. per annum—a rate which we believe to be almost without a parallel in the United Kingdom.

The Influence of Snake Poison.

DR. J. FAYRER, Professor of Surgery in the Medical College of Bengal, has published the results of certain experiments made to ascertain the effects of snake poison on large animals. The horses experimented on had been condemned to be destroyed, for a disease which, though incapacitating them from work, was not a disease which would reduce the strength of the animals to such an extent as to deprive the experiments of their value. The animals were a stud-bred mare, about 143 high, and aged twenty-seven years, suffering from partial paraplegia, and an Australian horse, 15.1, nine years old, a powerful animal, and in good condition, though also paraplegic. The mare succumbed in an hour and twenty minutes from the effects of the bite of a large cobra; while the stronger and younger horse survived the bite of a powerful, fresh, and full-grown daboia nearly twelve hours.

The difference in the effects of the poison of the daboia and cobra in these two cases is very remarkable, not only as to the duration of life in the animals bitten, but also in the pathological conditions before and after death. The mare bitten by the cobra was rapidly affected—staggered, became exhausted, and died in less than an hour and a half. The horse, bitten by the daboia, on the other hand, was affected very slowly, and seemed to doze his life away until just at the last, when a few unconscious plunges terminated his existence. It is to be noted, however, that the cobra bit more vigorously, forced his fangs deeper, and had to deal with a more feeble animal than the daboia, who bit a more powerful and healthy horse, and did not insert his teeth with such vigour as the cobra. The snakes were both fresh and full-grown, and their terrible power was strikingly illustrated by the death of these horses.

The Small-Pox in Melbourne.

THE very few cases of small-pox which have of late occurred in Melbourne, and the comparatively mild form in which the disease has manifested itself, would seem to indicate that the precautions taken to arrest its progress have been to a great extent successful. A report from the chief medical officer, submitted about a week since to the Legislative Assembly, affords some interesting particulars with respect to the epidemic and the measures adopted to prevent its spreading. The report states that the most minute inquiries into every one of these cases had failed to trace any contagious origin to them. The success of the sanitary measures adopted to stop the progress of the disease in every locality in which it had sprung up showed clearly that it did not spread by direct contagion, and it was believed that by a constant and persevering use of the same measures the disease would be finally stamped out. Dr. M'Crea's previously expressed hypothesis with respect to the disease being the result of "telluric and atmospheric influence" was reiterated and was considered as supported by the opinions of some of the European medical authorities. What, however, was of more importance as far as the public was concerned was pointed out also, namely, that primary vaccination in childhood does not protect a person from small-pox beyond a certain and that a very limited period, and that no person who had lately been properly vaccinated had taken the disease. Re-vaccination was held to be a complete protection against small-pox, and they who neglected it risked not only their own lives, but those of their fellow-citizens.

The College Election.

MR. SOLLY has secured his presidency. The other two councillors elected are Messrs. Erichsen and Gay. Both these gentlemen are pledged to support the right of Fellows and Members to elect the representative of the College in the General Medical Council. Mr. Solly is, we believe, favourable to the same cause. Mr. H. Lee was very nearly successful, and will be sure to get a seat very soon.

Royal Academy Sculpture.

THE art critic of the *Illustrated London News*, alluding to the progress of art as illustrated by this year's display at the Academy, thus criticises the works of one of the exhibitors:—"Mr. J. Lawlor made a marked advance. His nude figure of a man in strenuous action, entitled 'Lashed to the Helm' (1212), is unsurpassed for vigour and anatomical truth by anything here. His 'Musing' (1214), a gracefully disposed figure of a woman, shows close and careful observation of nature, whilst his 'Daute in Exile' (1247) is most impressively original, and the bold cast of the drapery highly effective."

IT is painful to learn that cholera has broken out again in H. M.'s 58th Regiment at Allahabad in the new barracks. The regiment has, in consequence, been broken up into detachments and quartered in the Clydesdale, Mansfield and Chatham lines.

A LETTER from Jhansi, dated the 31st ultimo, says—"A soldier of H. M.'s 93rd Highlanders died from heat apoplexy on the 29th, and another man fell down dead yesterday while on sentry, from *coup de soleil*. Among the

natives—both in the city and in the district—deaths from these two causes are numerous. If it does not rain soon I don't know what will become of us."

THE cultivation of poppy, says the *Indian Daily News*, is to be largely increased in the Bengal Presidency, and at once, in consequence of the proclamation of the Emperor of China, prohibitory of opium cultivation in any part of the imperial dominions, the issue of which we lately notified to our readers. The abandoned agencies of Seetapore and Rohilkund are to be immediately re-opened at a net increased charge of Rs. 4,000 a month. The fixed annual quantity of provision opium is to be 48,000 chests, with, in addition, a reserve of 10,000 chests to be gradually provided. The consequent necessary orders have been issued in time for the cultivation of 1869-70.

MEETING OF THE GENERAL MEDICAL COUNCIL.

ON Thursday last, at two o'clock, the Council commenced its sittings in the Library of the Royal College of Physicians, Pall Mall. There were present—

Dr. BURROWS, President, in the chair.

Dr. Bennett, Dr. Christison, Dr. Sharpey, Dr. Storrar, Sir Dominic Corrigan, Dr. Smith, Dr. Apjohn, Dr. Leet, Dr. Thomson, Dr. Fleming, Dr. Parkes, Dr. Andrew Wood, Dr. Alexander Wood, Dr. Embleton, Mr. Hargrave, Dr. Rumsey, Dr. Quain, Mr. Cooper, Mr. Hawkins, Dr. Paget, Dr. Acland, Dr. Stokes.

After the minutes of the last meeting had been read by the Registrar, one new member, Dr. Macrobin, was introduced to the President by Dr. Alexander Wood, and took his seat as the representative of the joint Universities of Edinburgh and Aberdeen, in the room of Professor Syme.

THE PRESIDENT then delivered an elaborate address, which will be found in another column.

SIR DOMINIC CORRIGAN rose to ask a question as to the status of the President of the Council, in consequence of a resolution passed at the close of last year's session, when Dr. Burrows expressed a desire to resign that position.

A long discussion followed, in which Mr. Caesar Hawkins, Dr. Andrew Wood, Dr. Christison, Dr. Smith, and Dr. Quain took part; and it was ultimately agreed that the President should occupy the chair until the close of the present session; during the interim, the members of the Council should consider among themselves the appointment of his successor.

The following committees were next appointed:—

Business Committee.—Chairman: Dr. Andrew Wood; Dr. Embleton, Dr. Aquila Smith, Mr. Caesar Hawkins, Dr. Leet.
Finance Committee.—Treasurers: Dr. Sharpey and Dr. Quain; Dr. Smith, Dr. Fleming, Mr. Cooper.

Committee on Returns from the Bodies in Schedule (A) of Professional Examinations and their Results.—Chairman: Dr. Embleton; Mr. Hawkins, Dr. Fleming, Dr. Thompson, Dr. Smith, Dr. Sharpey.

THE REGISTRAR then read the following letter from the Government upon the subject of the Medical Acts Amendment Bill:—

"Medical Department of the Privy Council Office:
May 14th, 1869.

"SIR,—With reference to the Draft Bill which you recently brought under the Lord President's notice, as proposed by the General Council of Medical Education and Registration, for amendment of the Medical Act, 1858, his Lordship directs me to inform you that, with every wish to assist the Medical Council in accomplishing its important duties, he does not feel that he could undertake to bring the proposals of the Draft Bill separately before Parliament, as a measure recommended by the Government, unless he regarded them as covering all the ground where amendment of the Medical Act is wanted; for, considering that the Act has at present been more than ten years in operation, the Lord President presumes that a fair judgment can now be formed on its success and merits as a whole, and he thinks that a judgment of this more comprehensive sort must be the basis of any amended Bill to be introduced on the part of the Government. The Lord President

would be glad to have the fullest possible explanations with the General Council on this larger aspect of the case, and though the requisite consideration could not be given to the subject in time for legislation in the present far-advanced Session of Parliament, his Lordship would hope to be able to deal with it next year in the light of such information as he may meanwhile receive.

"On the present occasion the Lord President does not propose to enter minutely on the question of the working of the Medical Act, but there is one point which his Lordship would wish to bring specially under your attention. His Lordship is advised that the Act is seriously defective, as not providing for a satisfactory and uniform minimum standard of admissibility to the *Medical Register*, and as not enabling the General Council to issue Regulations in this respect. The state of the law in the United Kingdom (unlike that which obtains generally in Europe in the same matter) allows a minimum qualification in Surgery to be registered without any qualification in Medicine, and similarly a minimum qualification in Medicine to be registered without any qualification in Surgery; and, so far as may be judged from a recently published analysis of titles contained in the *Medical Register*, it would seem that persons practising on those half-qualifications are to be counted by thousands in the United Kingdom. Cases are not unfrequently brought under his Lordship's official notice where persons possessing only such half-qualifications undertake nevertheless to act in all departments of professional practice, and even obtain engagements as salaried attendants on the sick poor in relation to whatever diseases or injuries may affect them. The Lord President regards this state of things as open to serious objection, and his Lordship doubts whether Government could sanction any amendment of the Medical Act which should leave so great an existing evil undealt with. The Lord President is of course aware that at the present time most of the Examining Boards which confer half-qualifications voluntarily extend their examinations beyond the limits of their titular qualification; but his Lordship doubts whether that mode of action, at its best, can supply more than a very imperfect substitute for complete legal qualification, and whether if it were universal and permanent, it would not itself tend to develop considerable new difficulties.

"The Lord President understands that the General Council will now very shortly enter upon its annual session in London, and he accordingly directs me to suggest that perhaps you would bring the above branch of the subject under the particular consideration of the Council, with a view to his being favoured with any recommendation which the Council may be disposed to make in regard of it.

"His Lordship further directs me to suggest that the same opportunity would be favourable for eliciting the opinion of Members of Council, whether, if new legislation is to take place it would be desirable to change in any respect the constitution of Council which the Act of 1858 established.

"I have the honour to be, Sir,

"Your obedient servant,

(Signed)

JOHN SIMONS."

"DR. BURROWS, F.R.S.,

President of the General Medical Council."

Three other letters were also read: from Dr. Prosser James, respecting the representation of the profession in the Medical Council; from Dr. Bell Fletcher—permission being given to this gentleman to head a deputation to lay the claims of 2,000 medical men who had signed the petition for more direct representation in the Council, on the following Wednesday—and from the Garioch and Northern Medical Association upon the same subject. These letters, for which we have not space, were ordered to be entered on the minutes.

The next business upon the programme was a motion by Sir DOMINIC CORRIGAN—

"That it appears desirable, before any further attempt is made to introduce amendments of the Medical Acts, that a commission of inquiry should issue to take evidence from such members of the Medical Council, and such other persons as the Commission may see fit to examine, with the view of furnishing a report to serve as the basis for legislation."

The consideration of this motion was, by permission of the Council, postponed.

Some recommendations from the executive committee, respecting the expenses of the Council's printing, were then read by Mr. CAESAR HAWKINS, which, he contended, would materially reduce the expenditure in this respect, without any inconve-

nience to the Council or interference with the proper working of the business before them.

Dr. PAGET, who seconded the series of resolutions proposed by Mr. Hawkins, said the expenses of printing had increased enormously, and it was therefore necessary that the Council should go into details in order to make the necessary reductions. Several other members spoke to the necessity for great reductions, and the recommendations were unanimously agreed to.

A list of those examining bodies whose examinations fulfil the conditions of the Medical Council as regards preliminary education, was then read:—

List of Examining Bodies whose Examinations fulfil the Conditions of the Medical Council as regards Preliminary Education.

I.—UNIVERSITIES OF THE UNITED KINGDOM.

OXFORD: Examination for a degree in arts; responsions; moderations; local examinations (senior), certificate to include Latin and mathematics.

CAMBRIDGE: Examination for a degree in arts; previous examination; local examinations (senior), certificate to include Latin and mathematics.

DURHAM: Examination for a degree in arts; examination for students in their second and first years; registration examination for medical students; local examinations (senior), certificate to include Latin and mathematics.

LONDON: Examination for a degree in arts; matriculation examination.

EDINBURGH, GLASGOW, ABERDEEN, ST. ANDREW'S: Examination for a degree in arts; preliminary examination for graduation in medicine or surgery.

DUBLIN: Examination for a degree in arts; entrance examination.

QUEEN'S UNIVERSITY (IRELAND): Examination for a degree in arts; entrance examination; examination for the diploma of licentiate in arts; previous examination for B.A. degree.

II.—OTHER BODIES NAMED IN SCHEDULE (A) OF THE MEDICAL ACT.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: Examination conducted, under the superintendence of the College of Surgeons, by the board of examiners of the Royal College of Preceptors.

THE SOCIETY OF APOTHECARIES OF LONDON: Examination in arts.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH; ROYAL COLLEGE OF SURGEONS, EDINBURGH: Preliminary examination in general education, conducted by a Board appointed by these Colleges combined.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW: Preliminary examination in general literature.

ROYAL COLLEGE OF SURGEONS IN IRELAND: Preliminary examination, certificate to include mathematics.

APOTHECARIES' HALL OF IRELAND: Preliminary examination in general education.

III.—EXAMINING BODIES, IN THE UNITED KINGDOM, NOT INCLUDED IN SCHEDULE (A) TO THE MEDICAL ACT.

ROYAL COLLEGE OF PRECEPTORS: Examination for a first-class certificate.

IV.—COLONIAL AND FOREIGN UNIVERSITIES AND COLLEGES.

UNIVERSITIES OF CALCUTTA, MADRAS, BOMBAY: Entrance examination, certificate to include Latin.

UNIVERSITY OF MCGILL COLLEGE, MONTREAL: Matriculation examination.

UNIVERSITIES OF TORONTO, KING'S COLLEGE, TORONTO; QUEEN'S COLLEGE, KINGSTON; VICTORIA COLLEGE, UPPER CANADA: Matriculation examination.

UNIVERSITY OF KING'S COLLEGE, NOVA SCOTIA: Matriculation examination; responsions.

UNIVERSITY OF FREDERICTON, NEW BRUNSWICK: Matriculation examination.

UNIVERSITY OF MELBOURNE: Matriculation examination, certificate to include all the subjects required by the General Medical Council.

UNIVERSITY OF SYDNEY: Matriculation examination.
COBRINGTON COLLEGE, BARBADOES: 1. English certificate for students of two years' standing, specifying the subjects of examination; 2. Latin certificate, or "Testamur."

TASMANIAN COUNCIL OF EDUCATION: Examination for the degree of associate of arts, certificate to include Latin and mathematics.

After a short discussion, the list was ordered to be placed on the Minutes.

The reports of the Branch Councils on the subject of a Board or Boards for conducting preliminary examinations, and respecting logic, were next brought forward and read.

Dr. FLEMING then proposed—

"That a committee be appointed to consider the reports of the Branch Councils, on the subject of a Board or Boards for conducting preliminary examinations, and to report their suggestions on the subject."

He said these reports take very different views of the question as to the propriety of a Board or Boards in each division of the kingdom being appointed on the authority of the Council to conduct the preliminary examinations. The English Branch Council are of opinion that it would not conduce to any improvement in the system to have such Boards. The Scottish Branch Council, on the contrary, recommend a system to be adopted over which control could be exercised, but are of opinion that the Medical Act does not authorize this Council directly to establish such Boards, but that it might be done in each division of the kingdom by the licensing bodies conjointly; while the Irish Council seem to think such a system would be very desirable did the legal rights of the different corporations permit it. With the view, therefore, of obtaining more information on this important subject, endeavouring to reconcile some of the conflicting opinions, and, it may be, form the ground for a clause in any amended Act, he moved, "that the reports which have been read be remitted to a committee for consideration."

Sir D. CORRIGAN observed that he warmly supported Dr. Fleming's resolution of last year, because it tended to ensure equality and sufficiency of education in general education for students entering the profession; and that he was as strongly opposed to Dr. Risdon Bennett's view, under which all control of the several licensing bodies over the kind and efficiency of the education in arts would be lost; for it would be perfectly impossible, even if the General Council had the power to supervise, month after month, no less than from forty to fifty forms of examination, for the number amounts to so much, some of these examinations being in Dublin and Galway, in London and Durham, in country towns in England and Ireland, and in like manner in Scotland, others in Calcutta and Madras, in Canada and Nova Scotia, in Melbourne and Barbadoes, in Sydney and Tasmania. The report from the Branch Council of Scotland, just read, explained so fully and so ably the objections to the system advocated by Dr. Bennett, of entrusting to others what should be done by ourselves, that he would ask the members of Council to give that report their attention. He knew no parallel instance for the system proposed by Dr. Bennett, of entrusting to others the examination of candidates for their several professions. He knew that the solicitors of Ireland did not confide to educational or examining bodies in almost every part of the world the examination of their apprentices, and ought we to do it? Surely, for the medical profession there is at least as much safeguard required as for the profession of a solicitor. Even though the Council were permitted to see the papers of those several examining educational bodies from all parts of the world, what security had they that, high as the papers might seem, the work was fairly carried out? What security can there be that papers do not get into the hands of candidates before examination? What security can there be that the persons to whom are entrusted the papers do not for bribe or payment let the papers get previously into the hands of those to be examined? They had not only no security against such an abuse, but good reason for believing that such things have occurred. What security is there that if one year a person competent to examine is appointed, there may not be next year or next month a person or persons quite incompetent to write even English appointed?

Sir D. CORRIGAN continued:—I hold in my hand a copy of questions issued at the "Competitive Examination for Appointments in the Engineer Establishment of the Department of Public Works in India," held at the India Office, London, in December, 1868, and I shall read for you some of the questions. It is—

ENGLISH GRAMMAR.

The following sentences are extracts from papers which were given to the Candidates, at the Competitive Examination for

Appointments in the Engineer Establishment of the Department of Public Works in India, held at the India Office, London, in December, 1868.

1. Use free-hand sketches or diagrams wherever possible, to illustrate the answer, which must be carefully executed, in order to show the Candidate's proficiency in this style of drawing.

2. Candidates must not during the Examination refer to any book or MS., nor communicate with each other.

3. Candidates are required to produce *bonâ fide* finished drawings, with certificate of their having been *solely executed* by the Candidate, respecting which there will be a *vivâ voce* examination.

4. State the reason why the tests employed by the Engineers in using Portland cement should be a compound one.

5. What is Portland cement? From what raw material is it made, and in what proportions are they used?

It may be objected that this particular examination is not of those recommended here; but this objection did not affect the principles that he advocated, "that our examination in arts should be under a Board appointed in Ireland, another in England, and a third in Scotland, above suspicion, which would ensure sufficiency and equality of education." If the student had already passed such an examination in the course of his education before any of the forty or fifty educational bodies named, there could be no harm in testing him. If the education he has already received is sufficient, then he would not suffer injury, for he would bear the test—there would be no hardship inflicted on him, and little or no expense, or expense so trifling—at most a few shillings—that it was not worth taking into account. If he be not able to pass the test of the Examining Boards specially appointed in England and Ireland, then he should and would be properly rejected.

Mr. CÆSAR HAWKINS did not consider that the document to which Sir Dominic Corrigan referred, and from which he drew such an amusing picture, had anything to do with the subject before them. It was for quite another and inferior portion of the community, and should, therefore, have no weight with the Council.

Mr. COOPER hoped the Council would not alter its views on the subject of preliminary education, and that the Examining Boards, as at present constituted, would not go beyond the limits assigned them by the Council. He could safely say that the recommendations of the Council were efficiently carried out by the Society of Apothecaries, of which he was the representative.

Dr. STOKES' experience was that, since the present system of preliminary education had been in force in Dublin, quite a different and more intelligent class of men had come up for examination, and he should therefore support the motion of Dr. Fleming. He would not say that the licensing bodies were corrupt, but that they had been no one at the table would deny; and he was of opinion that no greater safeguard against that disreputable class of students who formerly presented themselves existed than the admirable plan recently adopted by the Council.

Dr. EMBLETON hoped the Council would sanction nothing against the principles which had hitherto formed the basis of its enactments. He thought it would be a great mistake to fuse the branch licensing bodies into one common Board. The reforms introduced by the Council, and carried out by the existing licensing bodies, had been of great service, and were well worthy to be depended upon. He was, therefore, of opinion that the examinations should be left to the licensing Boards, as arranged at the beginning.

Dr. PAGET differed from a previous speaker, "that the Council had no control over colonial and foreign bodies." It had control, inasmuch that it could refuse to recognize the certificates or examinations of any of them; it had done so, and would do it again when necessary.

After a few further remarks, Dr. Fleming's motion, seconded by Dr. Alexander Wood, was put from the chair and carried by a majority of 14 to 7.

The committee was then appointed, and consisted of—Dr. Alexander Wood, chairman; Sir Dominic Corrigan, Dr. Bennett, Dr. Fleming, Dr. Leet, Dr. Paget, Dr. Storrar.

The following petition was then read:—

"To the Honourable the House of Commons in Parliament assembled:—

"The humble petition of the General Council of Medical Education and Registration of the United Kingdom,

"SHEWETH, "That the Council was established by the 'Medical Act' passed in 1858 (21 & 22 Vict., cap. 90), and was by a later Act (25 & 26 Vict., cap. 91) made a body corporate.

"That one of the principal duties of the Council is to keep and publish a register of such persons as have obtained or may obtain licences or other legal qualifications to practise medicine or surgery from bodies whose qualifications are recognized by the Medical Act, to the end that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners.

"That for the purpose of securing that all persons who shall be entitled to have their names and qualifications placed on the Register, shall have been duly educated, and tested by examinations, certain powers of inspection and of representation to Her Majesty's most Honourable Privy Council should need be conferred on the Council by the Medical Act.

"That the Council are of opinion that the interests of the nation require that the education of medical practitioners should be raised above its present standard, and that it is their duty to the extent of their powers to promote its improvement.

"That the Council are in the belief that a solid groundwork of preliminary general education is of the utmost importance to the successful prosecution of professional study, and that the greatest impediment to sound professional education is to be found in the defective early mental discipline of medical students.

"That, notwithstanding the desire of the several medical Corporations and Universities of the United Kingdom to comply with the recommendations of the Medical Council, that all persons previously to being recognized as professional students shall pass an adequate examination in general knowledge, the Council having reason to apprehend that the maintenance of a sufficient standard is rendered exceedingly difficult, owing to the defective and limited education generally given in secondary schools.

"That the views of the Council as to the defective state of secondary education is fully confirmed by the reports of the commissioners on secondary schools.

"The General Medical Council therefore pray your Honourable House, without delay, to pass such laws as may seem to your Honourable House to be best adapted to remedy the existing defects of endowed schools, and otherwise place the secondary education of the United Kingdom in a satisfactory state.

"And your petitioners will ever pray.

(Signed) "GEORGE BURROWS, M.D., President."

The Council then adjourned.

FRIDAY, JULY 2.

The members of the Council having answered to their names, Dr. ANDREW WOOD rose, in pursuance of notice, to move:—

"That a Committee be appointed to consider the question of the Amendment of the Medical Acts, and that to this Committee the communication from the Government on the subject be referred."

In introducing the foregoing motion, which gave rise to a long and animated debate, Dr. Wood said he considered they had received a good deal of mannerism from the Government upon the subject of education, but nothing solid. Sir John Gray, in the House of Commons, a few days since, spoke very strongly against the Council; and he felt justified in asking permission for digressing from the subject of the resolution in order to vindicate the Council from the aspersions cast upon them in the House of Commons. There was an impression abroad that the Medical Act and doings of the Council only concerned the profession. This was a very erroneous impression. It was well known that the object of the authors of the Medical Act was to pass such measures as would enable the public to distinguish between the qualified and the unqualified practitioner. The speech of Sir John Gray occupied the space of some three and a half columns of a newspaper; and if the statements sent forth through the press to the world remained uncontradicted, this impression would gain such hold on the public mind that it would be impossible to dispel. In Sir John Gray's speech upon the subject of the superannuation of Irish medical officers, he took the opportunity of introducing observations on the whole system of medical education. Sir John Gray had stated that "the Medical Act was a grievous failure." He said "that there was some petty

tinkering under that Act"—perhaps there had been a little—but the changes made, though tending to afford greater opportunities for the acquisition of knowledge, and increasing the expense to the student, failed to enforce a sufficient test as to the fitness of the candidate for being licensed to practise—or, more properly speaking, to experiment upon the lives of the subjects of the Queen." Sir John further said it might be inferred from some previous remarks "that one degree only was required by the Army Medical Board, while the Poor-Law Board required three, the natural inference would be that the qualification for the Army Medical Service is inferior to that of the Poor-Law Service, whereas, in fact, the Army Board would not appoint the holder of ten diplomas to take charge of a corporal's guard without testing him at the bedside as to his acquaintance with disease and his knowledge of the means of dealing with it. That Board accepts any registered holder of a diploma in surgery as a man who had given evidence that he received a good preliminary medical education; but they accept his diploma, and they are right, as proof of no more; and before they allow the holder of that degree (whether he has one or ten) to practise—to make experiments upon the valuable lives of the soldiers—they take him to the bedside and satisfy themselves that he is more likely to cure than to kill before they give the men over to his charge. This is not done by the several licensing bodies, and he (Sir John Gray) complained of the gross neglect of duty by the Medical Council in not having forced the licensing bodies to do this long ago." Such remarks as these, which he quoted from the hon. baronet's speech, would, he (Dr. Wood) hoped, be considered a sufficient justification by the Council for the course he had adopted. It was all very well for Sir John Gray to talk of forcing the licensing bodies. The Council had not the power to force those corporations to do anything. He (Dr. Wood), however, maintained that the wholesale charges made by Sir John Gray were a libel upon the Council. Could it be said with any truth that a great advance had not been made after the passing of the Medical Act? or maintained that the Council had neglected its functions? He wished to state publicly that it had not; but that each member had conscientiously and faithfully laboured to promote the interests of the profession in every way, and that great and lasting improvements amongst the licensing corporations had resulted therefrom. He admitted that in the time of Sir Benjamin Brodie, to which Sir John Gray had referred, the state of the profession was unsatisfactory. But had the Council not done very much since then for the elevation of those who presented themselves to be registered? It had been suggested that the model of preliminary education was pitched too low. This he denied; and he doubted if it were possible to introduce such a stringent course as had been mentioned as requisite in the University of London examinations. He believed if they attempted to raise the present standard too high the examinations would either become a sham, or they would tend to starve the public of a proper supply of medical men. What the Council had done had been chiefly by moral suasion; the best proof of the success of their action being that there was scarcely a licensing body which did not follow its recommendations. Sir John Gray had said that it was of no use to a sick or dying patient to know that his medical adviser was well versed in botany and scientific knowledge generally; what he would like to feel would be that he had been taught and admitted to practise from critical examination at the bedside. To this he replied, that there was not a ward in the hospitals of Scotland that was not constantly used for this purpose. He would, therefore, dismiss Sir John Gray from his mind by stating that he had misled Parliament by statements which had really no foundation in fact. In other quarters it had been said that the Council had done nothing. He would not occupy the attention of the Council except to mention one or two things that had been done. There was the Pharmacopœia, which was admitted on all hands to be the best in the world. There was the subject of the recognition of colonial degrees, which they had done much in; and by adopting a liberal policy, had shown the colonists our sympathy and desires to meet them on equal grounds. A general outcry had also been raised that the Council did not protect the profession against quacks. This he maintained it never could do; no registration could possibly effect this so long as men were found despicable enough to become quacks. On the subject of the constitution of the Council, he would suggest that as an answer must be given to the Government, that a committee

should be appointed to discuss the question. It would have hard and difficult work to do; but it was better that from the present agitation the profession should get a thoroughly good and comprehensive measure, and not by dribbles, as it had hitherto done.

Mr. HAWKINS rose to second the motion of Dr. Andrew Wood, and spoke at length upon the double and single qualifications granted by the various licensing boards, but his remarks were inaudible at the reporters' table.

Mr. COOPER said as some allusion had been made to the examination at the Apothecaries' Hall, of which he was the representative, he would remark that the examinations had been visited, and found to be in accordance with the recommendations of the Council. He would further state that any other suggestions or resolutions of the Council would be rigidly enforced. He did not conceive it to be necessary that so long as such an excellent institution as the Royal College of Surgeons existed there was any necessity for students at the Apothecaries' Hall to be examined in surgery; but in the practice of medicine he was of opinion that if a man passes the Apothecaries' Hall, including clinical examination, he was entitled to receive his diploma to practise.

Sir DOMINIC CORRIGAN said that Mr. Cooper had departed from the original motion, and he would not then take up the time of the Council with a further digression, but would cordially support the motion of Dr. Andrew Wood. With the permission of the Council he would, however, like to say a few words in defence of Sir John Gray, whose speech had been so severely handled. He much regretted the attack upon Sir J. Gray, who was not there to answer for himself. He was a graduate in medicine, and thoroughly interested in the welfare of the profession. Supposing, therefore, that a mistake had been made in any portion of the statements alluded to, was that a reason for such an attack? But he did not admit that Sir J. Gray had committed an error, for he contended with him that the Medical Act was a perfect failure. No one would be bold enough to deny this. If it were not a failure, then why seek to amend it? Admitted, then, that it was a failure, in that it had failed to produce a large number of men who were to be trusted with the lives of Her Majesty's subjects, had the Council produced anything more satisfactory since the passing of that Act? It had not done so, for the obvious reason that it had no power to enforce its recommendations. If he was told—as he had before been—that it had the power, then why not enforce it, and thus put an end to the reproaches of a dereliction of duty? Sir John naturally laboured under the impression that the Council had not the power, simply because it had never yet applied to the Privy Council to enforce it. He also differed from Dr. Wood, that the Council had raised the standard of preliminary education. His impression was that it had been lowered, for had not botany been excluded from the compulsory subjects, and others which were formerly required of students? He (Sir Dominic) could not understand such a sentence, "that if they insisted upon raising the standard they would not find men to supply the public wants," from Dr. Wood, who had been foremost in the ranks of education, and was himself probably one of the most highly-educated men in the kingdom. One reason for raising the standard would, in his mind, get rid of the now niggardly Boards of Guardians, whose opinion was that a half-educated man was quite sufficient for paupers. This reminded him most forcibly of the reply of his late friend Mr. Colles, when interrogated before a committee of the House of Commons on the subject. He was asked "If it were not possible to educate an inferior class of men for the treatment of the pauper?" His reply was, "I know of no other mode of curing the poor man than that adopted for the rich."

Dr. ALEXANDER WOOD was not at all surprised to find Sir J. Gray had a champion ready to defend him in the person of the learned Baronet who had just sat down, because the views of the two were so perfectly identical; but what he was surprised at was, that a man of Sir Dominic's intelligence should stand up at that table and assert that those sitting around had no right to criticise or attack a member of the Legislature, whether he was right or wrong in his assertions, on the ground that he was not present to answer for himself; that the Council was to be abused out of doors, and that the individual who, in his place in Parliament, thus spoke through the press to the whole world, was to be secured from all immunity to hostile criticism from those who sought to defend the body aspersed. He (Dr. Wood) could not agree that the Medical Act was a perfect failure; it was only so to a degree.

No measure was ever brought forward which was not susceptible of improvement; but it was no argument to assert that, because the measure was imperfect in some provision, that it was a perfect failure. He also objected that the Council should be continually taunted that it had no power to enforce its recommendations. If the body over which Sir Dominic Corrigan was the representative had defied them, it was certainly the only one. Again: in the visitation of examinations, they must look for an example of that recusance of which Sir Dominic complained. He denied that the Council had lowered the standard of preliminary education. A knowledge of several languages had been added to the curriculum, the examinations had been visited, and a committee was appointed to carry out the regulations. Botany was not now considered necessary, because the requirements in the examination on *materia medica* were deemed sufficient. He admitted that the present state of medical education was not all that could be desired, but it had been much improved, and he therefore objected to the taunts that were being continually thrown at them by Sir Dominic Corrigan, whose object seemed to be, whenever the Council sought to enforce any regulation, to knock them down, and then laugh when they were on their backs.

Dr. LEET explained that, from an allusion made by Dr. Wood, it would be inferred that the examinations of the Apothecaries' Hall of Ireland were conducted upon a somewhat lax principle. To this he would say that a more careful or more stringent examination of the licentiates was not adopted, or enforced by any Body in the United Kingdom, the complaints being that the examinations were so difficult to pass.

Dr. CHRISTISON said there was some truth in the remark of Sir Dominic Corrigan, that St. Andrew's University did not examine students clinically. This was a great mistake; and he felt certain that it had but to be pointed out to that Body by the Council, when it would be at once acceded to.

After a few words of explanation from Sir Dominic Corrigan, Dr. Andrew Wood, and Dr. Thomson, the motion was put from the chair, and carried without a dissentient voice; the Committee appointed to carry out the object of the resolution being:—Dr. Burrows, chairman; Mr. Hawkins, Dr. Paget, Dr. Quain, Sir Dominic Corrigan, Dr. Parkes, Dr. Apjohn, Dr. Christison, Dr. Bennett, and Dr. Andrew Wood.

Dr. PAGET then moved that the letters of Dr. Prosser James, and of the Northern Medical Society, which were read to the Council on Thursday, should be referred to that committee. Dr. James had propounded a plan which, without expressing any opinions upon it, he thought should form the subject for consideration.

The motion was seconded and carried.

Dr. STORRAR next moved, that the communications from King and Queen's College of Physicians, Ireland, the University of Dublin, the Queen's University in Ireland, and Trinity College, Dublin, respecting preliminary examinations, be placed upon the minutes. This motion was also carried; the communication from Trinity College giving rise to a very animated discussion, in which Dr. Apjohn, Dr. Storrar, Dr. Wood, and Sir Dominic Corrigan took part. This discussion had not finished when the hour for adjournment was called.

SATURDAY, JULY 3.

The Council assembled to-day at one o'clock. The minutes of the previous meeting having *pro forma* been read and confirmed,

Dr. ACLAND, as chairman, laid before the Council, the

Report of the Committee on State Medicine.

The State Medicine Committee, appointed June 27th, 1868, beg leave to report that in pursuance of the instructions they received, dated July 8th, 1868, they have forwarded to various persons at home and abroad the following Letter and Questions:—

32 Soho square, London, W., 1868.

Sir,—A Committee of the Medical Council has been appointed to inquire into and "to report on the steps proper to be taken, if any, for granting diplomas or certificates of proficiency in State Medicine, and for recording the same in the *Medical Register*, due regard being had to the interests of existing health officers in the several parts of the kingdom."

The Committee have decided that such diplomas or certificates ought to be granted, after due examination, to persons who are already, or shall hereafter be, entered upon the *Medical Register*, and to no others.

The Committee are about to draw up a report on the education which in their judgment is proper for such persons, the time it should occupy, and the mode of examination.

The Committee would feel much obliged to you if you would give to them your opinion on these points, and on any others which may appear to you proper to be discussed by them.

In order to assist you in arranging your answer, I venture to append a list of questions, by no means intending to limit the form or extent of your communication, but to indicate in certain detail the information the Committee desire to obtain.

A memorandum drawn up for another purpose is also enclosed.

Of course, the Committee do not presume to trouble you to answer those inquiries with which you may not be familiar.

The Committee desire me to express to you their hope that the national importance of this question may prove a sufficient excuse for the trouble they are giving to you, and that you will be kind enough to return an answer before November, to me, at the above address.

I am, Sir, your obedient servant,

(Signed) HENRY W. ACLAND,
Chairman of the Committee.

Questions.

1. Various subjects, such as forensic medicine, toxicology, morbid anatomy (human and comparative), psychological medicine, laws of evidence, preventive medicine, vital and sanitary statistics, medical topography, and portions of engineering science and practice have been suggested as those in which examinations should be passed by candidates for a diploma or certificate in State medicine. Would you state what are the subjects which, in your opinion, should enter into a programme for this purpose?

2. What is the time which should be exclusively given to these subjects, supposing it to be commenced after the completion of the ordinary period of medical study?

3. What might be the order of such studies? What should be the method of study adopted?

4. In which of these subjects of study would practical instruction appear necessary?

5. To what extent should the study of these subjects respectively be carried? Can you suggest any books which furnish an approximate standard of the knowledge you would recommend?

6. What are the deficiencies which you have observed in medical witnesses?

7. How would you propose to remedy them? by what education—legal or scientific?

8. How should a court of examiners in this subject be constituted?

The Committee desire to record their best acknowledgments for the great attention that has been paid to their request by the eminent persons who have replied to the questions.

Immediately following this report is an analysis of the answers from English correspondents. It has been thought desirable to keep this analysis distinct from the observations of the foreign authorities, whose letters cannot advantageously be dealt with in the same manner.

The answers from home and from abroad are all printed *in extenso* in an appendix.

Dr. Rumsey has favoured the Committee with detailed personal observations on the evidence, and although the Committee have not thought it desirable to embody those remarks in their report, they have thought it right to place them before the Council.

The Committee are unanimously of opinion that the evidence submitted in these documents warrants, and indeed demands, that the Council should insert the requisite clauses for providing a qualification in State medicine in any amended Bill which may hereafter be prepared for Parliament.

Should the Council see fit to agree to this recommendation of the Committee, the individual members of the Council will be able to give before the next session of the Council their serious attention to the details they would wish to see embodied in any scheme or bye-laws for carrying such clauses into effect.

This seems the more necessary, because, although there is a uniform testimony among all the correspondents of the Committee, that grave attention is due to the condition of public medicine in the present state of this kingdom, there is great discrepancy as to the duties to be assigned to officers for forensic and sanitary purposes, and as to the conditions under which these officers are to be appointed. The Committee are agreed that the thorough discussion of the question of appointments and duties in the Public Medical Civil Service has become essential for the progress of social administration and organization; and they think it reasonable that medical stu-

CHEMISTRY, &c.

ON THE FLUORESCENCE OF QUINIA.

PROFESSOR STOKES finds that if a solution of quinia in weak alcohol be touched by a rod dipped in diluted sulphuric acid, the beautiful fluorescence of the quinia is instantly developed. If another drop be similarly touched by a rod dipped with diluted hydrochloric acid no apparent effect is produced. Nor is this all. If a little hydrochloric acid be introduced by a moistened rod into the fluorescent drop, the fluorescence is immediately destroyed. If a little sulphuric acid be introduced into a drop containing only hydrochloric acid no effect is produced. If a series of drops of a solution of quinia in diluted sulphuric acid be taken, and a little solution of chloride of potassium, sodium, or ammonium be added, the fluorescence is immediately destroyed. On trying a variety of the acids, Professor Stokes found that, with hardly an exception, unless the acid character of the acid was indistinct, the acids arranged themselves into two distinct classes, A and B. Those of class A develop fluorescence in a solution of quinia in water just like sulphuric acid, and includes all the acids known under the name of the oxygen acids.

dents or practitioners (however few they may be who wish to devote themselves wholly to this branch of the public service) shall obtain a diploma, certifying the possession of knowledge adequate to the end in view—viz., the prudent and skilled care of the public health and the solution of forensic questions.

As the Council will have the opportunity, at some future period, of discussing the documents now submitted to them, the Committee do not consider it desirable at present to offer any detailed observations of their own; they recommend that the report and appendix be forwarded to the licensing bodies and other persons interested in the question of State medicine.—(Signed) Henry W. Acland, chairman; Robert Christison, George E. Paget, Edmund A. Parkes, H. W. Rumsey, Aquilla Smith, William Stokes, Allen Thomson.

July 3, 1869.

Before moving that the report be received, he begged to remark that the subject of State medicine was most certainly one of the growing questions of the day. Two years ago, when he first mooted the idea in the Council, he had been chaffed for his proposition of making State doctors; and he had also been asked, on the other hand, why he did not bring forward some definite proposition, or embody his ideas in some tangible shape. The Committee of which he had the honour to be Chairman had now done this; and he hoped that with the valuable suggestions of Dr. Rumsey, whose opinions on the subject were entitled to considerable weight, the report would be found of great service to the Council and to the profession. He further desired that the requisite clauses should be inserted in the proposed Medical Act, which, he trusted, would be carried during the present Session. With these few remarks he begged leave formally to hand in the reports with the appendix, in order that they should be placed on the minutes.

Dr. PAGER then moved, and Dr. ANDREW WOOD seconded—"That the petition of the Lothians' Medical Association be received and entered on the minutes." Carried.

As Chairman of the Committee, Dr. FLEMING moved—"That the returns of examinations from the Medical Departments of the Army and Navy, and from the India Office, be entered on the minutes."

This was seconded by Mr. COOPER, and carried.

Dr. ANDREW WOOD, as Chairman of the Business Committee, then rose to move—

"That the standing orders be suspended, and that, with a view of expediting the business of various Committees, the Council do now adjourn until Monday, at two o'clock."

Dr. QUAIN seconded this, and the Council resolved itself into the following Committees:—

1. On the Amendments of the Medical Act.
2. The Pharmacopœia.
3. Finance.

MONDAY, JULY 5.

The Council assembled at the usual hour, after the reading of the minutes. The case of Dr. Pattison—whose misconduct will probably be fresh in the memory of our readers in *Frewen v. Pattison*—was gone into. Dr. Pattison was now summoned before the Council to show cause why his name should not be struck off the *Medical Register*. This gentleman did not appear, but sent a letter, expressing regret, and begging the merciful consideration of the Council. Some strong animadversions were made upon his gross misconduct in the case above alluded to, and his name was ordered to be removed from the Register.

Dr. CHRISTISON'S motion, "That the Edinburgh University Calendar for Local Examinations for 1868 be submitted to the Committee on Preliminary Examinations, with a view to the Council receiving the Report of that Committee as to the sufficiency of the said Local Examinations to qualify students to commence their medical studies," was referred to the Committee.

A communication from the Royal College of Surgeons of England respecting vaccination was read.

An application from Mr. George Peterson Bernard to be reinstated on the *Medical Register*, whose name had been removed, in consequence of a false report of his death having been inserted in the *Medical Directory*, was considered, and the request granted.

The applications from Messrs. Evan Thomas and Thompson Whalley to be restored to the *Medical Register*, were peremptorily refused.

A communication from the Bishop of Christ Church, New Zealand, respecting the educational regulations of Christ's College, New Zealand, was then read, and the meeting adjourned.

Those of class B not only did not produce it, but destroyed it when produced by the acids of class A. This list shows that the classification made by the quinia reaction agrees almost exactly with the old distinction of ox-acids and hydracids. There is, however, one acid, hyposulphurous, which, in the quinia reaction, ranges itself with perfect definiteness in class B, but which is not usually ranked with the hydracids, except in so far as acids in general have been regarded from this point of view. There appear to be other analogies between hyposulphurous acid and the hydracids. It is known that a solution of chloride of mercury reddens litmus, but the blue colour is restored by an alkaline chloride, though itself neutral to test paper. The same effect is produced by hyposulphite of soda. This salt and chloride of mercury very readily decompose each other, but if a very dilute solution be used, the solution of chloride of mercury having been coloured by a little litmus, the first effects of the introduction of the hyposulphite is to restore the blue colour. It is also known that cyanide of mercury is hardly decomposed by oxacids, but is readily decomposed by hydracids. Now, if a solution of hyposulphite of soda be added to one of cyanide of mercury, the smell of hydrocyanic acid is immediately perceived.

It would, therefore, appear that there is a real difference of constitution between sulphuric acid and hydrochloric acid. Dr. Stokes' experiments would seem to point out that the isolation of $S_2 O_3$, the analogue of chlorine, would be less improbable than that of $S_2 O_2$, the analogue of sulphuric anhydride.

With hydrocyanic and hydrofluoric acid the reaction seemed doubtful. These acids belong to class B, as regards the feeble amount of fluorescence which they develop, but not to prevent the development of strong fluorescence by acetic, sulphuric acid, &c. Ferricyanide of potassium had certainly no such action as chloride of sodium, or even ferrocyanide of potassium, in destroying the fluorescence; but the deep colour of the salt prevented a satisfactory decision whether the acid belongs to class A, or resembles hydrocyanic acid in its action on quinia.

In a discussion that followed, Dr. Odling made the following observations respecting the composition of hyposulphurous acid sodium, hyposulphite is represented by the formula $N_2 S_2 O_3$, together with a molecule of water, and this molecule of water is essential not only to the hyposulphite of sodium, but likewise to all the hyposulphites. If now, instead of writing the formula of the sodium salt as above, we put it all together in the form $Na_2 H_2 S_2 O_4$, we have a formula which admits of being halved, and may accordingly be supposed to represent a double molecule of the sodium salt. If this be the case, the single molecule will be $NaHSO_2$, corresponding to an acid $H_2 SO_2$. It is therefore quite conceivable that this acid may be a hydracid in which the

basis hydrogen is connected with oxygen not directly but only through the medium of other elements. Thus :—

Hydracids.		Oxacids.

Hydrocyanic.....	H CN.	HO CN Cyanic,
Nitrous.....	H NO ₂ .	&c.
Hyposulphurous	H SO ₂ .	

PECULIARITIES OF THE RETINA OF THE HEDGEHOG.

MR. J. W. HULKE remarks that the distribution of the retinal blood vessels in this insectivore is most remarkable, from the fact that only capillaries enter the retina.

In all other mammals except the hedgehog, as far as known, the arteries, veins, and capillaries enter into the retina. In fish, amphibia, reptiles, and birds, the retina is absolutely non-vascular, the absence of proper retinal blood-vessels being compensated for in fish, amphibia, and some reptiles by the vascular net which in these animals channels the hyaloide, and by the highly vascular pecten present in other reptiles and in birds. Thus, it is possible to divide vertebrates into two classes, according as their retina is vascular or not.

RESEARCHES OF ZIRCONS.

Mr. Sorby, by further researches upon this subject, is inclined to think that the two distinct spectra observed by him in zircons is not due to the presence of two distinct earths, but that jargonite exists in two distinct conditions. We have great doubts if peculiar absorption spectra is always indicative of the presence of individual elements, and expressed an opinion that the discovery of two new elements from the observation of absorption spectra could not be considered proven until we had some collateral chemical testimony. Our views (vide Summary of Science) are borne out by some made by Mr. Crookes on some Optical Phenomena of Opals (Royal Society, April 23rd), in which he mentions an experiment (No. 12) which "gives a narrow, straight, and sharply cut line in the green; this might easily be mistaken for an absorption band, caused by an unknown chemical element."

DYNAMITE.

This new explosive compound of nitro-glycerine is said, on authority of the *Journal de Pharmacie et de Chimie*, to consist of a mixture of twenty-five parts of porous earth, with seventy-five of nitro-glycerine. This mixture is stated to have an explosive force equal to that of the same bulk of nitro-glycerine, and not to be subject to the extraordinary dangers appertaining to the latter substance.

ON THE INFLUENCE OF PRESSURE ON CHEMICAL PHENOMENA.

M. Cailletet has followed out these experiments with an hydraulic pump of some power communicating with a reservoir of iron, to which is added a tube of copper, which is again connected with a tube of glass. This tube he calls the laboratory. There is also an arrangement by which the pressure can be rendered constant, and can be regulated. When a turning of zinc is placed in the laboratory tube, and hydrochloric acid is added, it is remarked that the disengagement of hydrogen is decreased according to the pressure. On weighing the turning of zinc it was found that it had lost by the action of the acid—

When operating in the air	10.0
At a pressure of 60 atmospheres	4.7
" " 120 " " " " " " " "	0.1

The quantity of zinc dissolved is in inverse ratio to the pressure.

ON LIQUID SULPHUROUS ANHYDRIDE.

M. Sestini has published the following results as regards liquid "anhydrous sulphurous acid :"—Three decigrammes of white phosphorus were placed in contact with three centimetres of the acid; the phosphorus diminishes in volume, and the liquid becomes slightly yellow. The tube sealed was taken into the dark, but neither the liquid nor the phosphorus undissolved exhibited any luminosity. After some days, on opening the tube the liquid was found to be phosphorescent, and on evaporation it gave a residue of yellowish white phosphorus. Iodine slowly dissolved, and produced a yellowish brown solution. Bromine also dissolves. Sulphur was almost insoluble. On adding nitric acid, a white crystalline mass is got, which resembles that found in the sulphuric acid chambers.

PHARMACY.

ON THE EXTERNAL USE OF NITRATE OF MERCURY.

Mr. Hamilton Hutchison, in the *American Journal of Pharmacy*, proposes to use nitrate of mercury in place of citrine ointment. He used it dissolved in glycerine. We very much doubt, however, if such a preparation has similar properties to the ointment. Citrine ointment is not simply a mechanical attenuation of nitrate of mercury. The fatty compounds are chemically combined with the mercurial salt, it therefore becomes quite a distinct thing from a solution of nitrate of mercury. Another point is, that Mr. Hutchison proposes to use the proto salt; it is a mercuric salt that is chiefly used in the ointments.

Mr. Hutchison, in his essay, states that this salt has been prescribed considerably of late by Dr. John Neill, of Philadelphia, in solution in glycerine, which, he says, is an unsatisfactory preparation requires a great deal of attention, and is also tedious and troublesome to make, besides changing in colour and consistence.

Crystallized nitrate of mercury is prepared by placing 400 grains of mercury in a small capsule, and pouring on it 300 grains of pure nitric acid, sp. gr. 1.42. About 560 grains of the dried salt are obtained, and about 10 grains of mercury remain undissolved. Crystallized nitrate of mercury is soluble in glycerine, slightly soluble in alcohol, ether, and acetic acid. Theoretically, 344 grains of citrine ointment are equivalent to 43 grains of crystallized nitrate of mercury. As the salt is quite soluble in glycerine, the best manner of using it as a substitute for citrine ointment would be to dissolve forty-three grains in five drachms of glycerine, which is equivalent in proportion to that ointment.

Dr. Neill has used it in the proportion of twenty grains in a fluid ounce of glycerine, which answered his purposes better than citrine ointment. The crystals made with chemically pure nitric acid, sp. gr. 1.42, become dry and hard, and will keep for a long time, while those that are prepared with common aquafortis become deliquescent. The salt should be kept in a glass-stoppered bottle.

In the same Journal, Mr. Covell has been examining the formula for citrine ointment of the different Pharmacopœias. As regards the British Pharmacopœia, he says :—

"The quantities of British Pharmacopœia were taken. The mercury was allowed to dissolve by the aid of the heat, generated by the reaction, about 125° F.

"The oil and lard were heated to 200° F., when the solution of mercury, 125° F., was gradually added in portions of fl. ʒij., at intervals of two to five minutes, that the reaction might not be too violent, and easily controlled. The temperature after the first addition rose rapidly to 230° F.; after the second it fell to 226°; and after each succeeding addition of the mercurial solution fell to 219°, 216°, 214°, then rose to 220°, then fell to 218°, 200°, 190°, at which it remained until the reaction had apparently ceased. It was constantly stirred through the entire process. Loss in weight, 13-63 per cent.

"In the foregoing detailed experiments the writer has gleaned the following facts :—That heat within certain range of degrees, and nitric acid of at least sp. gr. 1.42 in excess (although the British Pharmacopœia process shows too much acid), is required."

The addition of the acid solution of mercury by Mr. Covell by degrees would, however, have the effect of making the product more acid. This is an infringement of the Pharmacopœia directions, which states that the solution is to be added to the melted fats. If the temperature is right a violent action sets in, by which the greater part of the acid is destroyed in oxidising the fat.

Correspondence.

PROSTITUTION AND ITS CAUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your impression of May 19th, 1869, there is an article on "Prostitution, by Charles R. Drysdale, M.D." I hope that you will allow me, by means of your journal, to protest against the doctrines promulgated in that article, as I believe them to be not only erroneous, being founded on a false and insufficient analysis of the causes of prostitution, but also as

being liable to be understood as inculcating practices immoral and vicious in the highest degree.

I grant that the condition of the poorer portion of the female sex is bad, that their wages, especially in towns, is altogether insufficient, and that the difficulty in many instances of obtaining remunerative labour is a cause of many of their number becoming prostitutes.

But, while acknowledging that poverty is a cause, I hold that it is only a very partial cause of prostitution, and, further, that the classes from which the greatest number of prostitutes come are not the very poorest. The appearance and manners of what may be called the more respectable prostitute are quite above those of the very poor.

The accuracy of Dr. Drysdale's assertion, "That a woman would, of her own accord, take to the precarious subsistence of a prostitute in this country for any length of time is an error,"—is I think, very doubtful. But be that as it may, once they have joined the ranks of prostitution they are very loath to leave them. There is a wild freedom in the life that charms them. Then, too, they have their own society, with its various ranks and gradations, like virtuous people; they are well clothed and fed, and, save the very lowest grades, are exposed to no hardships or privations. The number of women who are well fed, clothed, and paid, yet who follow the calling of prostitutes in their leisure hours, shows that poverty alone has not driven them to it. How many women may be seen in the day time standing behind the counters of shops, &c., who at night act the harlot?

To say that prostitution and poverty will ever cease to exist in this world is simply absurd. There will always be virtuous and vicious, rich and poor, no matter how many or how few the population. Were the population of a district ever so scanty, some would be idle, disreputable, ne'er-do-well, who would always be poor. Nay, start each member of a thinly populated district with an equal amount of wealth, and what would be the consequence? Why, in a short time some would have spent all their substance in riotous living and idleness, and others would have accumulated riches by thrift and industry. So that from the various natures and inclinations of men and women (leaving overcrowding out of the question), we have a rich and poor class formed. The disposition and training, not the numbers—the quality, not the quantity it is, of a people which decides the question of poverty or riches, a crowded population merely expediting the process.

Again, it is necessary for those who say that prostitution is caused almost solely by poverty and overcrowding, to prove that when there was no overcrowding there was no prostitution; or, since they assert that prostitution and poverty have the same exciting cause, over-population, that there has never existed either prostitution or poverty in thinly populated districts, that none but the poor have at any time become prostitutes.

Now, that the very reverse is the fact history proves by abundant examples. In very early ages indeed, when the land was certainly not overcrowded, we find from the history of Judah and Tamar, that prostitutes were a well-known institution, and that they were distinguished from modest women by certain peculiarities of dress.

The Jews in Solomon's time, and for long after, did not overcrowd the land, and yet they had both poor and harlots amongst them. In Athens, too, formerly the prostitutes were called *ξένοι*, "strange women," showing that although poverty existed in Athens the Athenian women did not become prostitutes. Corinth was famous for its harlots, "who were maintained in the temple of Venus and prostituted themselves for hire." In Rome the prostitutes were often of so good a family that they changed their names when about to become harlots, in order that they might not disgrace their family name. History therefore shows that in parts of the world where the population was thinly scattered, prostitution existed in a large proportion amongst those who were not forced to undertake that course of life from poverty.

Again, how does Dr. Drysdale propose to inflict a deathblow to prostitution by "early marriages, and very few children, (indeed, none at all, perhaps, as frequently in France for some years) and greater facility for divorce, as obtains at present in Indiana, United States, and some of the States of North America?" Now I believe I am correct in stating that in Indiana a mutual consent of the parties before a magistrate is sufficient to annul the marriage contract—how, then, does this do away with prostitution?

Why, like the Manichean doctrine of the origin of evil, it only removes the difficulty a step back, and substitutes a prostitution sanctioned by law instead of the present system; for it

is obviously the same thing, taking a wife for a certain time, then divorcing her, paying her for her services by money, food, raiment, lodgings, &c., and keeping a mistress in the same way. No doubt we shall soon see a proposal to return to the custom of the primitive Spartans for married men to exchange their wives, or lend them to deserving young men, and by this means put an end to prostitution. But the advocates for facility of divorce seem to have forgotten what the intelligent Author and moral Governor of this world has said about it. And it may not be out of place to remind them that He who is surely the best Judge of what is most suitable for His creatures, has decided that "what, therefore, God hath joined together, let no man put asunder." Again, how are the number of children to be regulated? or none at all to be begotten? This consummation can only be brought about either by the total separation or abstinence on the part of husband and wife, or by so limited a connection as would only excite, not allay, their passions, and would only be more conducive to the spread of prostitution, than to its extinction, or by practices too abominable and vicious to be entertained by any right-thinking people.

If anything were wanted to prove the detestation in which infantile murder before birth, rightly by our laws entitled "felony," and called in the statute book "criminal abortion," has been held from the most ancient times, it is shown by the obloquy in which those who made themselves *eunuchs* were held by the Jews. The only true way for the abolition of prostitution is by teaching men and women to exercise denial, to restrain the animal promptings of their nature within the bounds appointed by Divine laws, remembering that in this world they are in a state of probation, and that by overcoming and resisting the snares and allurements of vice they are fitting themselves for a future state of happiness and bliss.

I am, Sir,

Your obedient servant,

R. J. KINKEAD, A.B., L.M.T.C.D.

Medical Gleanings.

ICE IN AFFECTIONS OF THE TESTICLE.

DIDAY (*The Annales*) employs ice in some of the affections of the testicular apparatus: 1st, In orchitis, sometimes complicated by blennorrhagic epididymitis, he finds it serviceable; 2d, In testicular neuralgia; 3d, In certain states in which pain constitutes the predominant feature.

MEDICAL SCIENCE IN JAPAN.

An interesting account of the art and science of medicine amongst the Japanese is given in one of the American journals, by Dr. Vedder, an American physician, and now the chief medical adviser to the Prince of Nagato. The Japanese doctors hold very good positions in society. They originally derived their knowledge from the Chinese, but of late years the diffusion among them of Dutch literature has done much to their enlightenment. There are no schools of medicine in Japan, but the son scrapes together as much information as he may be able from his father, or the native practitioner dispenses his empiricism to the two or three pupils that generally reside with him. An attempt is being made to establish a school at Nagasaki, in connection with the hospital there, but it is likely to fail from the fact that Dutch is the only foreign language allowed to be used. Physicians carry a couple of swords, and special respect is paid to their opinions, although they are generally paid for medicine alone; and, as may be imagined, the latter is ample and bulky. Sometimes, however, a special honorarium is given to the doctor at the close of the treatment of a case. Very little is known of anatomy. There are native names for veins, nerves, lymphatics, and the principal anatomical structures, but topographical anatomy is entirely unknown, since dissection is not permitted. The Japanese are quite in the dark with regard to physiology. The liver they imagine to be the seat of courage. The doctor feels the pulse at both wrists at the same time, in the belief that there is a heart on either side of the body. There are a few works on tumours in Japan, the contents of which have been dictated by

fancy or the traditional accounts of disease. Foreign medicines, nevertheless, are in use now-a-days, iodide of potassium, Hoffman's anodyne, quinine, henbane, and phosphoric acid amongst others. These having been introduced into the country by the Dutch, who were likewise successful in importing the practice of vaccination some thirty-five years ago, which, however, is very loosely followed, notwithstanding small-pox everywhere prevails. The Japanese have no conception of such a thing as preventive sanitation. Skin diseases are propagated largely in the public baths. Midwives are the ordinary accoucheurs, but seek the aid of the native practitioner in cases of difficulty. Operative surgery is wholly unknown; fractures are treated by leeches and plasters. Crutches and slings are unheard of, but the moxa, bleedings, shampooing, and acupuncture are freely employed. It can be readily understood after this sketch what an alarming amount of life must be sacrificed in Japan to the prevailing ignorance of the first principles of the healing art. Tooth-drawing is an exquisitely torturing operation. The tooth is first loosened with a mallet and a short stick, and then extracted with the fingers. Pieces of the jaw often come away attached to the tooth, a circumstance we are not disposed to gainsay.

Medical News.

ST. GEORGE'S HOSPITAL.—The following important document has been circulated:—"We, the undersigned, having been appointed a committee to examine into the income, expenditure, and general principles of management of St. George's Hospital, beg to report as follows:—1. That there is no separate or selected Committee of Management; every governor is a member of the Weekly Board, and can record his approval or disapproval of any proposal brought before the Board; further, that the Weekly Board has not the power to sell out more than £1,000 stock at one time, without the sanction of a Court of Governors specially summoned for the purpose, and that, not only in principle, but in practice, the whole body of governors is responsible for the government of the hospital. 2. That the annual report of the hospital contains a most careful and detailed statement of the income, resources, and management, and that it appears difficult to draw any sound distinction between the donations of living persons and legacies left for the use of the hospital without any special direction as to their application. 3. That it seems to be the distinct duty of the governors to employ the funds given or left to them in meeting as far as their power extends the present and growing requirements of the sick poor, and that future wants must, if necessary, be met by the future contributions of the opulent. Under the sense of this public obligation, and under the constant pressure of the increasing population of the district, the governors since the year 1829 have raised the accommodation afforded by the hospital from 200 to 350 beds. The new wing, now ready for occupation, which will increase the accommodation of the hospital to 380 beds, has been built by the aid of a munificent gift from the Marquis of Westminster, a legacy of £5,000 from Miss Williams, and separate contributions specially applicable to that purpose. 4. That while it is impossible to carry on the hospital without a considerable reserve fund, it would appear unwise on the part of the governors to ignore, even at the occasional sacrifice of a small portion of that reserve fund, the growing wants of the community around them, inasmuch as the legacies are found to have increased in proportion to the increased efforts of the governors. 5. The fluctuations in the actual amount of the reserve fund have not been large, and the amount of the fund on the 1st of January, 1869, was (inclusive of real property), as nearly as can be calculated, a little more than £101,000. In the year 1829 the reserve fund was much the same in amount as at this moment, and since that period we have rebuilt the old hospital and increased the accommodation from 200 to 380 beds. 6. That the present expenditure of the hospital is not extravagant or excessive seems incontestably proved by the facts. (a) That, in spite of the greatly increased price of provisions and wages, the annual cost per bed is not larger than when the hospital had only 200 beds; and (b.) That the annual cost per bed at St. George's contrasts favourably with that of every other hospital in London. That having earnestly and carefully considered the important subject referred to

them, your committee are unanimously prepared to record their conviction that the general principles of management which seem to have guided the governors have been sound and prudent, and most conducive to the permanent interests of the public and of the noble charity placed under their care, and that in the details of that management there has been as strict and close an attention to economy as is consistent with the well-being of the patients and the permanent interest of the hospital.—Grafton, Penrhyn, Alfred de Rothschild, John Abel Smith, F. Haygarth, Lieutenant-Colonel, Augustus M. Meyrick, Colonel, H. G. Sutton. St. George's Hospital, June 19."

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS, not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

TO OUR READERS.—In the hurry of despatch last week, there were a few copies sent out without the lithographic illustration of Dr. Benjamin F. McDowell's valuable paper on "Lupoid Ulcer of the Leg." We shall be happy to send the illustration by post to those gentlemen who did not receive it in their copy.

The following Original Communications and Letters are in type, and will appear as soon as space permits:—

On Fibrous Tumours of the Uterus, sixth Lecture, by James Palfrey, M.D., M.R.C.P.

On Over-Population, by Dr. McMahon Murphy.

Dr. S., Letter-track.—We would most willingly give you every assistance in our power for the object you have in view; but, at present, it appears to be totally unattainable. The Bill as it stands includes everything that will be granted, and though by no means all that we could wish, we accept it as the best we can get.

MR. SHIRKWIN.—The type of your article was distributed before we received your note—or we should have had great pleasure in sending you some reprints.

"POISONING BY CHLORODYNE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In page 610, June 16, 1869, of your Journal a case is stated of "Poisoning by Chlorodyne." On reading it, I found that the "symptoms were markedly those of poisoning from morphia;" and further, it was confessed that the (so-called chlorodyne was made from the ordinary published formula, containing four grains of morphia to the ounce.

Now, I do not question for a moment that this poor woman died from morphia poisoning, but I protest against the statement that she died from chlorodyne. From the writer's own evidence she could not have done so, simply because she never had it; the appropriating the word "chlorodyne" to a sophisticated compound does not verify the substance, for the remedy for which I coined the word chlorodyne NEVER CONTRACTS THE PUPIL, a fact so significant, that it must strike the reader with astonishment after the published announcement of "Poisoning by Chlorodyne" where the gravamen of the remedy is founded on the circumstance of the pupil being contracted from morphia. The appropriation of the word chlorodyne to different concoctions is therefore wholly unjustifiable and unwarranted, for it logically stands to reason, if there is any fact in nomenclature, that two things possessing opposite action cannot be recognised or designated by the same name—at least, as regards therapeutic. As well may the thirsty traveller in the desert expect to slack his thirst from the mirage before him, as the prescriber of a spurious compound expect the same results as obtainable from a genuine medicine.

I am, Sir, yours faithfully,

J. COLLIS BROWNE, M.D., M.R.C.S. Eng.
(late Army Medical Staff).

DR. ZACHARIAH JOHNSON.—The letter on "Treatment of Fracture of the Thigh by the Weight and Pulley," is unavoidably postponed till our next.

VACANCIES.

Middlesex Hospital.—Lectureship on Materia Medica and Therapeutics.

Applications to be sent in on or before the 14th inst.

North London Consumption Hospital.—Visiting Physician. Applications to be sent in on or before the 16th inst.

Westminster Hospital.—Resident House-Surgeon. No Salary. Board and residence free. See advertisement.

Dental Hospital of London.—Dental House-Surgeon. Salary, £100 per annum.

Sheffield General Infirmary.—Assistant House-Surgeon. Salary, £65, with board and residence.

ESTABLISHED 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (KING'S COLL.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

KENT.—A first-class Family PRACTICE for transfer.

Average receipts, £700 a year (without assistant). Ample scope for increase. The best class of residents are included in the practice, and a very pleasant public appointment brings in £30 a year. No union. The house is a desirable mansion containing 13 rooms. There are extensive flower and kitchen gardens, stabling, coach house, greenhouse, and every convenience. Reference can be given to leading practitioners in London. Address X 597, Mr. Langley, as above.

STAFFORDSHIRE.—In a thriving District, an open SURGERY for TRANSFER. Upwards of £4 per week cash receipts. Dispensary well fitted. No Midwifery has been taken. Premium, to include fixtures and drugs, £120. Address X 606, care of Mr. Langley, as above.

YORKSHIRE.—In the suburbs of a Large Town, an excellent NUCLEUS for TRANSFER. Present income upwards of £200, but there is ample scope for increase. Convenient house at a low rent. The incumbent being about to enter into a Partnership elsewhere, will accept £150 for an effective introduction, fixtures, furniture, and drugs. Address X 604, care of Mr. Langley, as above.

SOUTH COAST.—For TRANSFER, a well established Family PRACTICE in a good town. Patients chiefly of the upper class. Income £900 a-year. Excellent house (containing 13 rooms), large garden, conservatory, stabling, etc. Rent £33. Address X 614, Mr. Langley, as above.

LONDON.—For TRANSFER, a good middle-class PRACTICE, yielding about £600 a-year. Appointments £150. About 40 cases of midwifery in a year. Lowest fee £1 ls. Large and convenient house in a good situation. Part of the purchase money may be paid by instalments properly secured. Address X 613, Mr. Langley, as above.

DEATH VACANCY, SOUTH WALES.—The SUCCESSION to a PRACTICE yielding £400 a-year, in a very picturesque district, is open for negotiation. Railway station near the house. Convenient house, with very large gardens and orchard, at a very low rent. Address X 611, Mr. Langley, as above.

PARTNERSHIP near LONDON.—The HALF SHARE of a PRACTICE yielding £1,000 a-year in one of the most attractive suburbs of London is open for negotiation. The district is rapidly improving, and there is great scope for increase. Premium 1,000gs. Address X 608, Mr. Langley, as above.

YORKSHIRE.—In consequence of failing health, an old established PRACTICE, in a beautiful district, is for SALE. Income £600 a-year. Expenses light. Complete introduction. Address X 607, Mr. Langley, as above.

LONDON SUBURBS.—For TRANSFER, with long introduction, an old established and increasing PRACTICE, with appointments. The receipts are upwards of £1,000 a-year, but there is great scope for increase in the hands of an active gentleman. Introduction to suit purchaser. Convenient house, with garden, &c., well situate for the practice. Premium, £1,000, of which £600 would be required in cash. Address X 616, Mr. Langley, as above.

MR. LANGLEY'S QUARTERLY LIST OF SELECTED PRACTICES and PARTNERSHIPS is now ready. Post-free for two stamps. Gentlemen seeking eligible investments, will find therein the description of about EIGHTY PRACTICES now open for negotiation.

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By JAMES PALFREY, M.D., M.R.C.P.,

Assistant Obstetric Physician to, and Lecturer on Clinical Obstetrics at the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

LECTURE VI.—PART I.

GENTLEMEN,—I propose to-day to continue the subject of the treatment of these submucous fibroids by describing to you the operation which I have now for some ten years been in the habit of performing, simply premising that I have not for a long time made any endeavour to remove, at the time of operating, any portion of the growth itself. Having satisfied myself that the tumour I am treating is of the submucous variety, and having carefully examined the patient with a view of ascertaining the condition of her other organs, and particularly her kidney, having carefully for a week or two previously regulated the condition of her bowels, I usually, some three or four days before the commencement of the ensuing menstrual period, have the os uteri leeched. During the whole of that period I advise the patient to remain quietly in bed; and as the decline of the menstruation is indicated, I again have some four or six leeches applied to the cervical portion of the uterus, this time followed by a warm bath. On the morning of the third day from the entire cessation of all bleeding, I administer a gentle purge; and having thus reduced to a minimum the congestion of the uterus, I proceed, on the morning of the fourth day, to operate. (I say on the morning of the fourth day, because I have found, in performing any operations upon the sexual organs, that by operating early in the day the patient not only recovers from any sickness or other inconvenience that may follow

the administration of chloroform, but also regains before night that mental quiet which every woman loses when aware she has to undergo any surgical proceeding, no matter how simple; so that, as a rule, their night's sleep is not at all interfered with.) Early, then, having had the patient placed upon a firm table—none better than an ordinary narrow dressing table so common to our bedrooms—and being thoroughly under the influence of chloroform, I have her brought well to the edge of the table, and in the lithotomy position, an assistant taking charge of a knee on either side, which must, during the whole time, be kept well flexed upon the abdomen. I next introduce a Sims' speculum, one of large size, fixed upon a straight handle, which gives greater power in depressing the perinæum than the ordinary double-bladed duck-bill speculum. Having brought the os uteri well into view, I give the speculum into the charge of a nurse, who is instructed to kneel at the left of the operator, being prepared with some six or eight small fine sponges attached to long slender handles of cane; with a pair of fine slightly curved vulsellum forceps I then grasp the anterior lip of the uterus, giving the handles of the vulsellum into the charge of one of the gentlemen commanding the knees. Next I introduce *into* and *through* the os uteri internum Sir James Simpson's single-bladed hysterotome, having previously adapted the blade to the identical depth I wish to cut on either side; with this instrument I make a bold and free incision, first into one side of the cervix, then into the other. And here please to remark that this portion of the proceeding differs very considerably from the operation we perform for the relief of those cases of dysmenorrhœa depending upon a narrowing or other mechanical obstruction in the cervical canal; in those cases we cut *up to*, but *not into*, the os uteri internum. Completing the incisions of the cervix, we pause for a moment, for it is at this stage, if at all, we get some free bleeding; and should this happen, do not be at all alarmed: sponge the cervix well out with small sponges dipped in iced water, and in a very few moments the bleeding, as a rule, will cease. Certainly, in my own hands it has but on one occasion given us the slightest anxiety, and in that case

we ought never to have operated, for we subsequently discovered that the patient was the subject of old Bright's disease; and this case is the only fatal one that has occurred to me in 119 operations. The next step is to cut into the growth itself, still preserving the steadiness of the uterus with the forceps in the anterior lip. I next pass into the uterus a very long probe-pointed knife, or rather saw, for it is more like a miniature saw than anything else I can name; this instrument I introduce sideways, guided as far as possible by my finger, wholly into the uterus; then, according to the position of the growth either in the anterior or posterior wall, I turn its serrated edge towards the surface of the tumour, and with a slow, yet firm and decided movement, I cut my way into the growth, and, assuming for the sake of description the growth is in the posterior wall, I introduce the index-finger of my left hand into the rectum, and supporting the enlarged uterus in this way I cut slowly and deeply until the depth of the knife in the growth, and its distance from the surface of my finger in the rectum, lead me to believe that I have made an opening through the greater part of the diameter of the tumour; then turning this saw-like knife with its edge to the right, I make a lateral cut in that direction, and subsequently doing the same into the left portion of the growth. This part of the operation I have never seen attended or followed by any notable bleeding. This finished, it only remains to introduce into the vertical jagged incision in the tumour one or more long narrow strips of lint, well wrung out in olive oil. This step in the operation requires some management, and at first will give you some little trouble. Do not rest, however, until you have firmly and securely plugged the whole of the incision and also the cervix; follow this by plugging the whole vagina with the plug of balls of cotton wool, tied at small distances to a length of whip-cord. This form of plug possesses the great advantage of being instantly removed at pleasure, and, in addition, we avoid the pain and discomfort which attends the use of separate strips of lint or other material, which, if closely packed, as they ought to be, into the vagina, cause some trouble and considerable pain in their removal. Now, let me ask you most carefully to practise this plugging; it is, I assure you, a very important part of the proceeding, and the part the careful performance of which effectually protects you from the anxiety, and the patient from the peril of any subsequent hæmorrhage. Very much of late years has been written of the dangers of this operation, and on more than one occasion I have been present at our societies when earnest debates have taken place concerning the fatal cases that have, in the hands of operators of the most undoubted skill, now and then occurred. I tell you, Gentlemen, fearlessly, that if you will adopt the precautions mentioned in my last and the commencement of this present lecture, you need have but little fears, indeed, of hæmorrhage in these cases. Keep your patient well chloroformed until this plugging is over, for it is the most painful portion of the whole operation. To proceed, then. Having securely plugged up to the vulva with this continuous plug of cotton wool soaked and wrung out in oil, a thick pad of folded lint upon the external organs, secured by a tightly applied T bandage, completes the operation. The patient is now removed to bed, and I usually at this time administer a third or half a grain of morphia by the hypodermic syringe. Should any sickness follow, I avoid giving anything for a few hours by the mouth, save now and then a tablespoonful of iced milk, or a little lemon-water ice, which is usually kept down and much liked by the patient. As soon as all fear of vomiting is over, some light nourishment may be given, followed, if necessary, by a little champagne or other light wine. As a rule, the pain following this operation is not sufficient to demand the regular administration of opium or any other sedative, and I have long discontinued its use in these cases unless called for by special circumstances. Towards evening, or earlier, should the patient complain of distension, the bladder must be emptied by the catheter; and this method of relief must be continued until the

whole of the vaginal and cervical plug has been removed. Should no untoward circumstance contraindicate this course, the *vaginal* portion of the plug may be removed twenty-seven or thirty hours after the operation, and the vagina should then be very gently washed out with a tepid douche. At the expiration of forty-eight hours I remove the cervical and uterine strips of lint, and then, having again washed out the vagina and lower segment of the uterus, I replug the cervix and as much of the uterus as possible, in the same manner as at first, removing the lint and replacing it every morning. This process is attended with a considerable discharge of an offensive odour. Do not be alarmed at this; it proceeds, I believe, from the softening and breaking down which is going on in the interior of the growth, through the capsule and into the centre of which you have made an opening. Continuing your treatment in this way, you will soon notice a sensible diminution in the size of the whole organ, more especially, however, in that portion of the uterus in which the growth was developed, the organ will become less fixed and more movable. I continue to use the cervical plug until four days before the next menstrual period comes round, and then I allow the uterus a few days of perfect quiet. I cease in every way to interfere either with the tumour or the uterus, and upon the appearance of menstruation your patient herself will become sensible of a marked improvement in her condition: the severe pain which has ushered in the bleeding will appear no more; the bleeding itself will be far less in quantity, and its continuance will be limited to three or four days; the bearing-down will gradually disappear—in fact, her troubles will grow less month by month. Careful examination from time to time will convince you that the growth is gradually becoming smaller. Some months will elapse before the tumour will become so small as to cease to be of the slightest importance or cause of danger; but, I assure you, with care this result will be accomplished. I do not tell you that all evidences of the presence of the growth will be lost; such a case has never happened to me, but with the exception of the one fatal case I have mentioned, I have in *no* instance failed in bringing about an arrest in the hæmorrhage, and a positive and well-marked decrease in the tumour itself. To go back for one moment in our details. I will observe that it is not necessary to keep the patient on a milk or slop diet long after the operation; usually on the day following I suggest some white fish, chicken, or sweetbread; and by the fifth or sixth day you may safely allow her to resume her ordinary mode of living, nor will aperients be necessary. I always allow the bowels to act themselves. I am sure I have seen serious irritation produced by the premature administration of purgatives after obstetric operations. I advise you to keep the patient very quiet until the menstruation that follows the operation is well over; not that it is wise to confine her to the bed during the whole of that time. My own plan is to remove her to a couch on the third or fourth day, and keep her there during the day until the appearance of the bleeding, when I advise her to remain in bed until it has wholly ceased. Now, you may inquire, and with much propriety, whether the performance of this operation in the manner I have endeavoured to describe to you is attended with equally successful results when the growth is situated in either wall of the uterus? I reply, Certainly not. I can hardly tell you why; but I am convinced that when the growth is found in the anterior wall, the benefit to the patient is less decided and less rapid in its appearance than when the posterior wall is the seat of the disease; not that the arrest in the bleeding is less certain, but I believe the tumour more slowly and less surely undergoes destructive changes when situated in the anterior than in the posterior wall. Possibly this may arise from the circumstance, that, when cutting into the growth we do so less deeply and with much more caution, knowing that the bladder intervenes between, our hand supporting the uterus externally, and our knife in the cavity of the organ; which anxiety is absent when cutting into the posterior wall, for in that case we can very accu-

rately measure the distance between the point of our finger in the rectum and the knife in the uterus. I would not have you imagine that I have operated upon these 119 cases without meeting with some difficulties, and not a few anxieties: on three occasions I have had to treat and guide the patients through an attack of pelvic cellulitis; in two other instances pelvic abscess has followed the operation; in both cases, however, this accident has followed premature exertion undertaken by the patients. But, notwithstanding the chance of such untoward symptoms and accidents occurring, I am firmly convinced that the results of this procedure are highly satisfactory to the operator, and truly beneficial to the patient. It is no part of my intention, in delivering these Lectures on Fibrous Tumours to you, to occupy your time with the narration of a series of cases to prove the value of the treatment I have just sketched out to you; but I feel confident you will gain some confidence in the operation itself if I briefly put before you the particulars of one or two typical examples; and I will begin with an instance of fibrous tumour in the anterior wall.

On the morning of the 19th August, 1864, Madame K. brought to my house a note of introduction from my friend Mr. Wm. Allingham, of Finsbury Square. I abstract from my notes the following brief history, taken at the time:—"Madame K., æt. twenty-eight, married eight years, no children, no miscarriages, was perfectly well until about a year before marriage, when her period commenced to be more profuse than before. This trouble has gradually increased upon her ever since her marriage, and, notwithstanding that she has had the best of advice in Switzerland, in which country she has resided, and also in Paris on various occasions, she is now in a state of complete exhaustion and profound anæmia from loss of blood; has had four separate attacks of hæmorrhage in the last seven weeks; her bladder also is extremely irritable, she being compelled to pass her water every twenty minutes, and this trouble keeps her from sleeping at night. A watery discharge always follows the bleeding; she has continual bearing down, but little pain in defæcation." I had no difficulty in recognizing a hard submucous fibroid, the size of an orange, springing from the anterior wall of the uterus, which was anteverted and pressing heavily upon her bladder. I pointed out to this lady that I could hold out to her no hope of relief whatever from drugs, and then explained to her the nature of the operation I proposed to perform for her relief. She immediately consented, and a few days after her visit to my house I saw her with Mr. Wm. Allingham, who fully agreed with me as to the nature of her malady, and coincided with me in the advice I had offered. Madame K. having been kept from this time perfectly quiet and constantly nourished, we proceeded on the 24th of September, 1864, four days after the cessation of a bleeding, to operate upon her. Chloroform having been administered by Mr. Wm. Allingham, and assisted by two other gentlemen, I operated exactly in the manner I have described above. I will not tire you by detailing the after treatment, suffice it for me to tell you that the bleeding at once ceased. This lady in a few months wholly recovered her health, and I believe has remained well up to this time. She favoured me with a visit in the summer of 1868, when visiting England; she then assured me she was quite well, and capable of undergoing very considerable fatigue; that she menstruated regularly, her period never lasting more than four days.

Let us next take a case in which the growth was situated in the posterior wall. On the morning of the 12th December, 1867, Mr. Talbot King, of Hackney, brought to my house, for my opinion, a lady, Mrs. C., æt. forty-three, a woman of full habit, married twelve years, never pregnant, commenced to menstruate at twelve years of age; always regular until six years ago, when her period became profuse in quantity, and preceded with severe pain. These symptoms, with the other indications of fibroid disease, have gradually increased, the bleeding during the past year being so serious on more than one occasion as to im-

peril her life, and keeping her in her room for months together. A long time elapsed before she would allow Mr. King to ascertain the nature of her malady; when he examined her, however, he had no difficulty in detecting a fibrous body of considerable size springing from the posterior wall, considerably dilating and enlarging the cavity, and expanding the neck. The condition of affairs becoming so alarming, the constant bleeding demanding the equally constant use of the vaginal plug, Mr. King persuaded her to see me. I fully corroborated his opinion, and plainly pointed out to Mrs. C. that her only hope of relief lay in an operation. She consented, and on the 27th December I operated. Mr. King in the most kind manner carried out my plan of after treatment, and her progress to health was so steady and satisfactory that I had occasion to see her but once after the operation. He writes me concerning her, in answer to my inquiries, on the 22nd March as follows:—"The operation was most successful; Mrs. C. has had no return of the flooding whatever since; she is now in excellent health, and can walk comfortably a long distance."

Now and then pregnancy follows the disintegration and diminution of these submucous growths. Some sixteen such cases have occurred to me; the following is a fair example:—Miss J., æt. twenty-six, a tall girl, exceedingly exsanguine in appearance, was brought to my house on the morning of Feb. 26, 1867. I learned that she had been in bad health for several years, her great complaints being intense pain in the uterine region and loins for many hours before each menstruation, and an enormous loss of blood on each occasion; the relative who came to me with this lady described the dysmenorrhœa as being "fearful" for hours. This girl had latterly been on repeated occasions delirious with the severity of the suffering, which was aggravated by vomiting and headache. The continuance of these troubles had been followed by epigastric pain after each meal, which had induced this young girl to abstain as much as possible from eating solids. Her bowels were constipated, seldom acting more than once in ten or twelve days, and then with great pain and distress, which arose from a mass of highly irritable hæmorrhoids which protruded at each evacuation of the bowel. I was further informed that Miss J. had been under the care of a considerable number of physicians during a period extending over five years. She readily acquiesced in the request I made to examine her uterus, and I found the whole organ very much enlarged, *completely* retroflexed, the body of the organ, acutely bent upon the cervix, lying in the hollow of the sacrum, was exceedingly tender and painful when pressed, and the slightest attempt at moving it was attended with great pain, the cervix was looking towards the pubic arch, which was gaping and œdematous, and also highly sensitive. After very considerable difficulty I was enabled to pass a fine silver uterine probe $4\frac{1}{2}$ inches into the cavity, and then introducing my finger into the rectum, which was perfectly flattened by the enlarged uterus, I found a growth springing from the posterior wall, bulging into and distending the cavity; the anterior wall of the womb, which was thin, was, by a little drawing down, easily moved over the growth and the probe. I suggested that I should see this lady with her own medical man, and a few days after her visit to my house I visited Miss J. at Peckham Rye with Mr. Shillingford, who, having then examined her, coincided with me as to the nature of this case. Both the patient and her friend immediately consented to the proposal I made to operate upon this case. I having previously explained to them that in my judgment drugs were wholly helpless to serve her, Mr. Shillingford very kindly undertook the preliminary treatment; and on the morning of the 20th of March, four days after the cessation of a bleeding, assisted by Mr. Shillingford, and Messrs. G. McKenzie and Edward Flint, of the London Hospital, I proceeded first to cut freely into the cervix, and afterwards into the growth. I saw her repeatedly with Mr. Shillingford. She progressed both steadily and satisfactorily; the following period *commencing* in the

night during the patient's sleep, and without her knowledge, it lasted four and a half days, and was moderate in quantity. I heard from time to time of this lady's progress, and some seven or eight months after the operation Mr. W., a member of my own profession, called upon me to ascertain my opinion as to the advisability or otherwise of Miss J. being married. I could see no objection to the step being taken, for I had but a short time before examined her and found her uterus in excellent position, 2½ inches long, and her general health all we could desire. Shortly after this she was married, and this step was followed by an increase in the quantity of blood discharged at each menstrual period, but without any accompanying pain. Several months later Mrs. W. called upon me to say she had missed five periods, and she had every reason to believe she had quickened. I requested her at once to go home and remain in bed during the remaining portion of her pregnancy. I saw her at her residence at Hackney a few days after this in consultation with a Mr. N. Kennett. The fetal heart at this time was distinctly audible. We did not, for a reason presently to be mentioned, examine her internally. I saw her again with Mr. Kennett some weeks later, and promised, should any assistance be required, to be present with him during her labour. On the morning of the 23rd of March, 1869, at half-past eight, Mr. W. called at my house to tell me his wife was in labour, and to request me to go and see her. I had but half-an-hour previously left London to attend a consultation at Dover, and upon my return from that place the same afternoon at five o'clock, I learned from Mr. Kennett that he had delivered her safely some three hours before my arrival of a well grown healthy child. We saw Mrs. W. together; she was then in excellent condition, and I heard subsequently that she made an unusually rapid recovery. It was but a few days since when passing her house I saw her nursing a very healthy looking child at her window. Now I have related to you this case in detail because to me it has proved in all its aspects one of the greatest possible interest and encouragement, and I feel sure it will be equally interesting to every one of you. You will observe that I said that I refrained during her pregnancy from examining this patient *per vaginam*. My reason for not doing so was simply this: While I held the post of Physician to the Metropolitan Free Hospital, we operated upon an exactly similar case. Ten months after being dismissed cured the patient presented herself, being then nearly six months advanced in her first pregnancy, although some sixteen years married. Our then Resident Medical Officer there being with me at the time was anxious, like myself, to ascertain the condition of the cervix, we both examined the woman; this was followed the same night by labour pains, and twenty hours subsequently she was delivered by our House Surgeon of a boy. This woman has been occasionally under my care at this Hospital since that time, but she has never again conceived. I have always entertained a strong impression that we interfered with her cervix sufficiently to induce contraction, which, extending to the uterus itself, resulted in the premature expulsion of its contents.

(To be concluded in our next.)

Original Communications.

ON ENDOSCOPIC EXAMINATION OF THE CAVITY OF THE WOMB.

By D. COMMANDER PANTALEONI, M.D.

THE greatest advances made by medicine in this century owe their origin mostly to an improved system of examination of the organs affected in illness, and to a clearer knowledge, that practice has therefore acquired of the real

state and different changes of those organs in illness. How much do we not owe to the system of auscultation of percussion and to the *stethoscope* introduced in medicine? What wonderful changes has the *speculum* and its use introduced in our knowledge of the diseases of the female sex? The discovery of the *ophthalmoscope*, the application of the same physical principles to another instrument the *laryngoscope*, created a new science for the diseases of the posterior part of the eye, and for the organs of the voice. And so any new instrument or system introduced to determine better the material either pathological or physiological changes, which take place in the human organism, will prove to be always an addition to our knowledge, a useful contribution to the practice of medicine.

The discovery of the ophthalmoscope and laryngoscope led to the invention of another instrument, the *Endoscope*, directed to the examination *by vision* of the internal organs, where no common light can be thrown, as it can be done in the examination of the larynx or of the eye. A further difficulty accompanied therefore the invention of this instrument; the necessity which existed of throwing a considerable quantity of light in an internal dark cavity, and that generally to be done through a narrow tube, as those organs do not generally communicate externally, but by narrow canals. Dr. Desormeaux, of Paris, was, undoubtedly, the first who invented a good instrument for this object, to which he gave the name of *Endoscope*, and Dr. Cruise, of Dublin, improved it very much by the introduction of a better light, and in a way of preventing the instrument from becoming heated by the burning of the light. It is always the instrument of Dr. Cruise that I have employed in my practice, and I am so well satisfied with it, that I owe a public testimony of thankfulness to its inventor, for the kindness with which he treated me in Dublin, and his willingness to show to me the employment of this instrument on several cases.

It was with Dr. Cruise's endoscope that I first examined a lady, who declared to me that she had been affected for nearly thirty years with a chronic coryza, or catarrh of the nose, and chiefly on the left nostril, and which no physician had succeeded in curing. It was not difficult to imagine first, and discover afterwards with the aid of the endoscope, the beginning of a polypoid vegetation on the mucous membrane of the nostrils, and through repeated cauterisations, and the injections of astringent liquid, to cure entirely an affection most troublesome, and which had made the patient very miserable.

It was three years afterwards, that the same lady, aged about sixty, consulted me to know if it was regular at her age to still lose blood by the vagina, as she was doing so daily, although in a small quantity. I declared immediately that she had most probably some fungous vegetations on the mouth and cervix of the womb, and I proceeded to an examination with the speculum, having already prepared everything to perform the cauterisation, if the case required it. Unfortunately, I found *nothing* on the neck of the womb or vagina, which could explain the hæmorrhage, and very seldom I met a cervix presenting itself so healthy to the speculum, although offering to the finger a little retroversion. I was, however, so convinced of the exactitude of my diagnosis, that I declared to the patient that the illness was only existing higher than I thought, and it must have its seat inside the cavity, and very likely towards the posterior part of the womb, and giving, therefore, origin to the slight retroversion of the organ. I determined, therefore, to proceed to an internal examination of the cavity of the womb, and to make use in this circumstance of the endoscope, as I had several times proposed to my most honoured and respected friend Dr. Sims to do; a thing, which I am not aware, as yet, has been ever attempted or done by any body else; and this is the reason that has determined me to bring to the notice of the profession the description and result of this case.

Everybody knows how Dr. Sims proceeds to the introduction of the sponge tent through the canal of the cervix

of the womb, being only a modification of the practice of the first inventor of the system, Sir James Simpson. I followed the system of Dr. Sims; and only as I had no assistant (as it is very difficult to have one in the common practice) I have always experienced a little more difficulty than he does in the introduction of the sponge tent, being obliged either to do it without any speculum, or to use only one hand, and therefore give up the help of the tenaculum to keep firm the womb, at the same time that the sponge tent is introduced and forced in. However, with some patience this difficulty is soon mastered. I leave the sponge tent always in for twenty-four hours, recommending to the lady to keep quiet at home, and possibly to lie down. I found once, that my patient took a long walk, and no inconvenience whatever followed, but I think with Dr. Sims, that it may perhaps prove dangerous to forget such a precaution and that we ought therefore to insist upon it.

The next day I proceeded to the removal of the sponge-tent. I had the lady lying on her left side, as it is usual in England in specular examinations or confinements, and I took the only precaution, that the lady should be as near and as much out as possible on the borders of the bed, as otherwise the lamp of Dr. Cruise's instrument might set fire to the curtains and at all events the endoscope be not so easily managed. Dr. Sims in his excellent work disapproves of the practice of removing the sponge tent in the lateral situation of the lady, and after the examination he directs the woman to lie on her back, and he then proceeds to the removal of the sponge and introduction of the finger for the digital exploration of the cavity. And certainly this system is the only practical one for the *digital* exploration, but I could not follow it, without again turning the woman a third time on her side, as the application of the endoscope is almost impossible if the lady lies on her back. The reason quoted by Dr. Sims against the removal of the sponge in the lateral position of the woman is, that the column of air precipitates itself inside the womb at once, and may, by its pressure, produce an irritation or an inflammation of the organ. I could never believe much in such an explanation; but knowing what a diligent observer he is, I always apprehended some mishap from following a plan, which he had occasionally seen dangerous. However, till now, I have not had, fortunately, any reason to confirm myself in those apprehensions.

The removal of the sponge, although made with the greatest precaution, produces always some bloody discharge, and as soon as the sponge tent was removed, I introduced, with the greatest ease, inside the cavity of the womb a cylindrical tube No. 30 of the *filière* of Charrière, and of the length of twenty centimeters; and constructed in such a way as to be perfectly adapted to the usual endoscope. In fact, it differed only from the usual tubes of Desormeaux by its being shorter, and by having suppressed the lateral openings existing in the urethral tubes of Desormeaux. Having in such a way applied the endoscope I could see most clearly in the inside of the cavity of the womb, and inspect the condition of the internal membrane. A polypous vegetation was easily discovered at the bottom of the cavity and towards the posterior part of the *fundus uteri* in my case. It was of a vivid red colour, unequal like a sponge, and of the largeness of a small strawberry. It was striking the difference with the pale yellowish colour of the rest of the membrane. I withdrew the endoscope fixing the tube however, upon the vegetation, and I introduced the caustic through the tube itself, being therefore quite sure of the impossibility of touching anything but the vegetation itself, and then each time, I looked in again with the endoscope to certify the effect of the cauterisation before removing the tube. I was obliged to return six or seven times to the use of the caustic. I employed the nitrate of silver, the chromic acid, which I have experienced particularly useful, and I would have willingly tried the caustic of Filhos and Bonnafond, which I have so frequently and so advantageously employed on the neck of the womb, but I could not find any means of reaching with those caustics at twenty centimeters distance. The cauterisation performed,

I always plugged the vagina with some cotton wool, to prevent the running of the caustic on the outside, as the nitrate of silver employed to the neck of the womb produces always a great pain to the outside parts without this precaution, and I have imbibed generally the cotton wool with a solution of chloride of sodium to decompose the nitrate of silver when I used this caustic.

I never saw the slightest inflammation of the body of the womb, or of the peritoneum through the employment of strong caustics or of the injections of a strong solution of iodine. In one case even my solid nitrate of silver broke, and a large piece was left inside the womb; but I had learnt already from the excellent work of Dr. Courty, how innocuous was this accident; and the patient felt no inconvenience of any kind from it. The reason of this innocuity evidently lies in the mouth and canal of the cervix being widely opened; and therefore the injected liquids or the secretions produced by the cauterisation running out freely; and my experience is in this point in accord with that of the best gynecologists, that the accidents produced by the injections even of simple water were due to the circumstance, that the fluid being not free to run out from the womb was either forced through the fallopian tubes in the peritoneum or even kept inside of the womb, acting as a kind of foreign body upon it.

The case to which I make allusion, and whose treatment gave origin to this article, proved to be one of the most perfect success, and with no return of the illness; but this case is not the only one where I employed this system of exploration. I have applied several other times with a negative, but not an unpropitious result. In one case of the most obstinate and frightful repeated hæmorrhage, where I had destroyed several fungosities round the mouth of the womb, served to prove that the lady was perfectly cured, and I could send her safely to some iron springs, where in a month or two she recovered the most brilliant health. In another case it authorised me to employ freely some perchloride of iron locally, and internally the ergot of rye. The hæmorrhage, which existed for several months, ceased immediately, and it did not return but with the regular menstruation and in the regular quantity.

Those facts authorise me to think that this system of exploration may occasionally prove very useful to the practitioner. What objection could be raised against this system? It is scarcely necessary for me to answer an objection made by a colleague, who boasted that he could always with his finger reach to the same conclusion without any visual examination. It is exactly the same objection that practitioners of the old school raised against the use of the speculum. All the discoveries made by the use of this instrument, and the complete change introduced in the science of gynecology through it, is the best answer to be given to such an objection. Besides, there is no practitioner who does not know how often it is extremely difficult, if not impossible, to perform a digital exploration of the cavity of the womb; at all events, the dilatation of the canal of the cervix for the digital exploration ought to be at least double of the one required for the introduction of my tube. But there is another, by far more important, consideration. Even supposing that the digital exploration should be equally conclusive, in what way can it help to the treatment? Instead of that in my system, the tube of the exploration offers at the same time the only possible means to bring remedies on the cavity of the womb without touching either the vagina, or the canal of the cervix, or the mouth of the womb, and therefore it introduces also a new system of cure as well as of exploration.

Those considerations decided me to put under the judgment of the profession this system, in the hope to open a door to some future progress of our knowledge in gynecology.

THE ANTIDOTE.—The country around Pumpkin Creek, Georgia, is very sickly, and there is such a notorious prevalence of chills and fever in the district that it is the invariable custom to pass quinine pills with the dessert.

THE TEMPERATURE OF THE AIR IN UPPER CANADA, WITH REMARKS.

By J. P. H. BOILEAU, M.B.,
Assistant Surgeon, 29th Regiment.

THE extreme coldness of the air in winter is one of the peculiarities of climate which distinguishes Canada from the other home and colonial stations of the British Army. During my leisure hours I constructed a table from observations taken by myself and Captain Simpson, of the 29th Regiment, and comparing this with a similar table constructed from the Kew observation I was so struck with its peculiarities that the thought occurred to me—surely some elucidation of local diseases is herein to be found.

For the space of three months the temperature fell every twenty-four hours below Fahrenheit's freezing point; eleven times it was below zero, and on one occasion the highest reading for thirty-six hours was 0. A short time before the great and rapid thaw or "freshet," which in a few days melted away the whole of the winter's snow and ice, we felt a degree of cold indicated by -12° . At that time who could have imagined that in less than four months deaths from sunstroke should occur? Yet such was the fact. In July, hundreds of deaths were properly attributed to such a cause. On the 14th of that month I recorded a true shade temperature of 101.5° .

This extraordinary difference between winter and summer is but typical of the great diurnal range, and diurnal variations which are characteristic of the Canadian climate. The extent of the diurnal range is a peculiarity which deserves notice. Thus, I have seen a temperature of 46° in the day, followed by 26° at night; a temperature of 25° by -2° , a temperature of 23° by -1° , 38° by 11° , 65° by 30° , 25° by -11° , 40° by -2° : here we have examples of ranges of temperature during the twenty-four hours amounting to 20° , 23° , 24° , 27° , 35° , 36° , and 42° . And the seasonable fluctuations are as great. A natural query is, "Do not the troops suffer in consequence?" I believe I am correct in saying, No. They certainly did not during the winter I am now speaking of, 1867-68; unless there might be some subtle and inappreciable effect to be rendered evident only by time. Officers, men, women and children enjoyed excellent health, whilst the ever-changing temperature varied from 47° to -12° . And this in a regiment whose last two winters had been passed at Malta, where for three years the lowest temperature recorded on the scanty grass of that barren sandstone rock was 37° above zero, and where the equability of the climate was such that the mean daily range varied from 7° to 12° only.

But the extent of the diurnal range is not more worthy of notice than the diurnal variations. Thus, to quote a few examples.

On the 12th of the month (the coldest day of the season) the mercury in the thermometer never rose above zero, falling as low as -5° . About this period we had a most violent snow storm, that far and wide deeply covered the ground; and the piercing cold froze every drop of water in our rooms, defying double doors, double windows, and heated stoves. I saw the water splash from my morning tub frozen into a sheet of slippery ice, before I had dried myself. Yet, in four days we had a temperature of 30° ; the lowest for two days being 20° .

On the 18th December, the temperature again fell below zero, but, *mirabile dictu*, in three days we had the thermometer marking 44° , with a minimum of 27° at night. We felt quite hot again, and the thousands of tons of snow that covered the ground disappeared; so that on the 26th of December, not a particle could be seen in the neighbourhood, nor as far as the eye could reach along the wooded shores of Lake Ontario; in fact, on the 24th December, the minimum temperature at night was no lower than 31° ; but soon it went down again. On the 30th of the month, the temperature varied from 24° to $+9^{\circ}$.

On the 3rd January, we had a temperature of 39° , on the 6th; -2° , the maximum not exceeding 9° .

On the 23rd January, we had 42° ; on the 27th, -2° ; maximum being 18° .

From the 30th to the 1st February inclusive, the lowest temperature was $+10$. Yet on the 2nd of the month we had -11 ; but this was followed in three days by 36° ; the minimum being 19° .

On the 20th of February, the maximum was 46° , and the lowest temperature at night was 19° , which was the maximum of the following day; the temperature falling as low as -2° ; thus, in the forty-eight hours we experienced a range of temperature amounting to 48° .

On the 26th February, the lowest temperature was 24° . On the 2nd March we had -12° . This was the last struggle of the Winter King. On the 3rd March, the lowest night temperature was -1 ; on the 4th, $+5$; on the 5th, $+16$; on the 6th, 39° ; and in a few days all the winter's snow was gone; every low-lying place a lake; every hollow in the fields a pond; every road a sheet of running water; every ravine in the hills bounding a swiftly rushing torrent. Every day we had now a temperature over 35° , and although at night it fell below 32° , so retarded the melting effects of the sun's increasing power, the latter won an easy and decisive victory, and the Canadian winter was gone.

On the 17th March, the temperature of the air had reached 65° , and we felt it very hot indeed.

In July, we congratulated ourselves and felt quite cool, when the temperature was as low as 70° ; so little is the absolute temperature of the air an index of our sensations.

The cold air of winter is most invigorating. As to our suffering inconvenience from these temperatures below zero, (local papers give a minimum of -18°) I don't think we had much annoyance. The truth is, of course, that we very seldom felt these extremes of cold, as we were moderately well housed, and very well clothed. At the same time it is an error to suppose that a large amount of thick clothes and furs are constantly required. It is not so. Driving, they are absolutely necessary, nor could sentries perform their duties without them. For all work in the open air at night they are required, but for ordinary pursuits during the day they are as often an inconvenience and discomfort as a benefit. Such may not be true of Lower Canada, but I am not writing about the climate of Montreal or Quebec.

The stillness and dryness of the air enable us not only to bear with, but to enjoy our out-door exercises whether the thermometer varies from zero to 32° : and this is the average winter temperature of Upper Canada.

The experience of ourselves and others justifies me in saying that the necessity of very warm clothing being constantly used is much exaggerated.

Only one case of frostbite occurred in the regiment, and if the man had not foolishly placed his senseless hand over the stove, in all probability he would have escaped any bad consequences. But enormous bullæ formed; the skin, and in some places the subcutaneous tissues, sloughed almost entirely from the fingers, leaving indolent and painful ulcers, which were most obstinate in granulating. He is now doing his duty, and, with the exception of a slight stiffness, the hand is as useful as ever. The affection was treated as a severe burn, one of Dupuytren's fourth degree. No case proved fatal during the cold season; in fact, we had not any serious case in the hospital. The sick list was remarkably low, and made up almost exclusively of accidents, or those well-known diseases which are generally admitted to be independent of climatic conditions, and the terribly hot weather, which we experienced during the months of July and August following, caused a large mortality. If any dweller in the tropics happen to read this paper, let him remember that here we have no verandahs, no punkahs, no tatties or other appliances, which in notably hot countries render the heat somewhat endurable.

We had in the regiment during three weeks more than twenty-four cases of intermittent fever; the duration of the

cases varying from five to twelve days. They were cases of true intermittent fever of the quotidian or tertian type. The maximum temperature of the paroxysm amounting in nearly all to 104°, or 105° F., relieved by the most profuse diaphoresis, and followed in a few hours, not by remission, but by complete absence of pyresia, the thermometer showing a normal or a lower than normal temperature.

I would here suggest for consideration the connection that there is doubtless between this marked range of temperature in the human body, and the marked and excessive range of temperature in the climate.

In my remarks on fevers prevailing in the Mediterranean, published in the last volume of the *Army Medical Reports*, I often used the word "sameness" to express the character of the symptoms; and in that climate the diurnal range is very small, the annual shade range scarcely exceeding 60° F.

It appears to me, that the analogy between the climatic vicissitudes of temperature and the local fever type is such as to imply a connection between them; the difficulty in associating the thermal characters of the locality, as a cause of the peculiarities in the fevers, is mainly due to the fact that many causes combine to determine the occurrence and the course of a disease; yet, through all this obscurity it appears to me that the variability, or constancy, &c., of a climate may determine the very characters of continued, remittent, and intermittent. Here we have variability marked in both; there we have constancy or sameness a character of each.

In speaking of Malta, I said, "No loss to the island if quinine were banished from it." In the Upper Canada summer of 1868, I was, on the other hand, bound to admit the absolute necessity of using it.

May I repeat what I have already stated: Is it not possible that the character of a fever in respect of its being continued, intermittent, or remittent, may be dependent on the thermal characters of the local climate? It is certain that heat alone does not cause fever; but I think there can be no doubt about its modifying fever; the question remains, what is the particular modification which it produces. I suggest the above. At the same time, remembering that my experience does not justify me in asserting anything, I admit that these considerations are more the result of abstract reasoning.

But personal observation is not such a *sine qua non* of all judgment as to hinder us from making a suggestion.

My reflections on this subject are the result of the expressed opinion of authority that malaria although a frequent, is not a necessary accompaniment of paroxysmal fevers. The evidence on this question being too strong to admit of doubt I looked for another cause, and my limited experience pointed to the thermal peculiarities of the local climate. It would seem, that the products, or, more correctly, the process, of organic decompositions is a cause, if not the only cause of fever,—that is, fever independent of primary local lesion; but there must be, I think, some other cause for the modification of the disease in respect of its being continued or paroxysmal.

THERAPEUTICAL MEMORANDA.

THE OXALATE OF CERIUM IN THE VOMITING OF PREGNANCY.

By J. WARING CURRAN, L.K. and Q.C.P.I., L.R.C.S.I., &c.

THE object of the present paper is to bring more prominently forward the valuable therapeutic action of the oxalate of cerium in controlling the distressing nausea of pregnancy. Most practitioners have at one time or another experienced the difficulty of finding a successful remedy for the alleviation of this most disagreeable concomitant of the parturient state when it arises, and a few perhaps at the cost of their professional reputation. Baf-

fled as others have been in getting hold of a successful agent to counteract the vomiting of pregnancy, experimenting with every new remedy likely to prove efficacious, adopting the favourite formula of reputed obstetricians, and exhausting every available and plausible method of treatment without reliable success, I became induced to prescribe the oxalate of cerium, and I can assuredly testify with the best effects and the most satisfactory results. Doubtless there are many remedies which temporarily subdue the incessant nature of the vomiting by neutralizing the acid generated in these cases; but none with the *permanent* and salutary advantages of the drug I advocate.

I administer it in the form of pills, as follows:—

R. Cerii oxal.

Ext. lupuli aa gr. 24.

Div. in pil. xij, cap. j. ter in die.

and at the same time exhibit bromide of potass in ten-grain doses with the tincture of yellow cinchona bark and spirits of ammonia. The mixture and pills appear to constitute a most successful plan of treatment.

At my suggestion Dr. Pultney, of Huddersfield, has given extensive trial to the oxalate of cerium; and in a communication just received from that gentleman I learn that he is preparing for publication the successful issue of a number of cases treated by cerium, some of which, previous to its administration, had evinced serious symptoms.

Hospital Reports.

MERCER'S HOSPITAL.

VARICOSE STATE OF SAPHENA VEINS, ERECTILE TUMOUR OF THE FOREHEAD, EXTERNAL HEMORRHOIDS TREATED SUCCESSFULLY BY THE INJECTION OF TINCTURE OF PERSULPHATE OF IRON.

By MR. MORGAN, F.R.C.S.I.,

Surgeon to the Hospital, Professor of Anatomy, R.C.S.I. &c.

THE radical cure of varicose tumours by a safe and speedy method is a subject of great practical interest. Various have been the means devised, but the direct introduction of some fluid for the purpose of causing coagulation in a special point, is doubtless one of the most powerful influences.

The persulphate of iron or "Monsel's Salt" presents the advantages of being nearly destitute of caustic properties, while it is a most powerful blood coagulator, the quantity required for use is extremely small, and its action is very rapid. I have used it during the last few months with much advantage.

The following cases illustrate successful treatment both where the vein in its entire course was more or less dilated, and where the chief disease was an abrupt dilatation:—

NO. 1.—ENLARGEMENT OF THE VEIN FOR ITS ENTIRE COURSE.

A young woman of twenty-three, a housemaid, suffered so much from the varicose condition of the saphena veins of both limbs that she had to give up her occupation. There was on admission, February 11, 1869, much pain and uneasiness from the over-distension, which rest, bandaging, and keeping the limb in an elevated position relieved. She also suffered from a mild febrile attack for the first ten days she was in hospital.

I then injected five drops of the persulphate tincture of iron in two places below the knee, taking great care to isolate the two points; a coagulum formed in about fifteen minutes, and the part of the vein between these two points also became dense.

The vein soon became occluded; no ill consequence resulted; the injected points were tender for the first four

or five days after the injection. The patient was allowed gradually to use the limb, and was able to return to her situation March 30.

NO. 2.—IRREGULAR DILATATION OF THE VEIN.

A woman who had been actively engaged as general servant was admitted to hospital on April 5, 1869, suffering from an immense cluster of varicose veins on the inside of the leg; it formed a large tumour, three inches broad and four long. The vein generally was not enlarged above the knee, but there were other dilatations below this point. The skin was extensively discoloured, but there was no ulceration. Owing to the great pain and uneasiness, the patient was unable any longer to continue at service and earn her bread. She was tired of palliative treatment, so I determined on the radical cure by the injection of persulphate of iron. Immediately above the dilated mass five drops of the tincture were introduced, and also immediately below, where the vein was free enough to have pressure made, and to be isolated. In about ten minutes a coagulum formed at each point, and after an hour the dilated portion became also firm, feeling like a cast of a varix. From this date, April 8th, till her discharge on the 21st, there was no unfavourable symptom; she was anxious to get home, which I allowed her to do, though I had wished her to remain longer in hospital.

In a week she returned with the upper cluster a little tender from friction and over-exertion. The vein itself still remained occluded. After some days' rest in bed all irritation had passed off.

NO. 3.—ERECTILE TUMOUR OF THE SCALP TREATED BY INJECTION.

A strong boy, aged eight months, was admitted to the hospital suffering from a large erectile tumour over the frontal bone; the circumference equalled that of a shilling, and its height half an inch. The surface generally was red and vascular; the integument on the summit was very thin, and became much distended from the crying or exertion of the child. As the case was a tolerably urgent one, and favourable for the use of the injection, I isolated the tumour by adhesive plaster strips, and then by a circular piece of stout pasteboard, I injected four drops of the persulphate tincture, taking care to break down as far as possible the interior of the tumour with the point of the injecting canula. The parts immediately around the injection point became condensed and firm to the touch; no inconvenience followed. A few drops of blood that escaped were coagulated by a little of the tincture applied on a point.

After six days the part of the tumour where the injection point had not been applied was injected with five drops of the tincture, and the interior broken up by the point of the canula; a small central slough followed this. General coagulation and occlusion of the vessels took place; the child was allowed home. The tumour being now depressed in the centre, and the circumference still a little elevated and firm, save at one point at the edge which was not reached by the fluid, but so small that I did not think it necessary to adopt any procedure further. When the child cries or uses any exertion there is not the least increase in size or attempt at erection.

NO. 4. EXTERNAL HÆMORRHOIDS TREATED BY INJECTION.

Two favourable cases of very large external hæmorrhoids having presented themselves, I used the persulphate injection with much success.

The projecting masses were seized in an ordinary slide forceps, and three drops of the persulphate of iron tincture injected into each. Coagulation took place in a few minutes, and the patients got permanent relief; the tumours becoming dense and full of coagulum were effectually occluded. I have found the persulphate of iron quite to equal the expectations attributed to it, and to merit the recommendation given it by Dr. Gross, who remarks (p. 848) that by its means he is satisfied, "that any case of arterial or venous tumour, unless very bulky, may be promptly and effectually cured."

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.,

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

MR. PORTER'S CLINIQUE.

Importance of Rounding the Edge of the Tibia in Amputations through that Bone.

MR. PORTER exhibited to his class a man aged thirty-four years, whose leg had been amputated by him eighteen days previously, for extensive disease of the os calcis, attended by ulceration of the neighbouring soft parts. He called their attention to the operation which he had performed—that at "the place of election"—and to the good stump which resulted. He had used no dressing, save cold water, and during the last few days a little chlorinated solution, and the lines of incision were now almost entirely healed, and certainly were as nearly well as if carbolic acid, or any other application, had been employed. But the particular point to which he asked their attention, was the importance of carefully rounding off the anterior edge of the tibia in this and other amputations through that bone. There was a great tendency for the anterior flap, which in this operation is composed of skin to ulcerate over the end of the tibia, and in order to avoid that consequence, he had found great benefit in not merely sloping the saw in the beginning of the operation, removing it, and re-entering it at right angles to the long axis of the bone, or in cutting straight across at first, and then sloping off the prominent anterior edge, as generally recommended; but in making only one cut, using Butcher's saw, and sloping it during the entire of the division of the bone, so as to round off the end in a gentle curve from its anterior to its posterior edge. He made this a constant practice, and he had never found the bone to cause any disagreeable after-effects in a stump thus formed.

Femoro-Popliteal Aneurism treated by Compression.

MR. PORTER also drew the attention of his class to a man under his care, suffering from aneurism of the lower part of the femoral artery, just where it joins the popliteal. He had been for some days under treatment, both digital and instrumental compression having been used, and the tumour having become nearly consolidated. We purpose publishing this case at length.

COOMBE LYING-IN HOSPITAL.

SOME CASES OCCURRING IN THE PRACTICE OF DR. KIDD.

Hæmorrhage from uterus, accompanied by great pain—Soft polypus exposed by tents of sea-tangle, and removed by écraseur—Uterus swabbed with strong nitric acid.

Mrs. E., æt. thirty, married, has two children, miscarried twice, was admitted into the Coombe Hospital, May 22nd, 1869. She had been under Dr. Kidd's care about a year before, and at that time he removed a soft polypus which grew from the fundus of the uterus. The account of the previous operation, and the history of her case before the first time of her admission into hospital, will be found in Dr. Kidd's paper "On the Diagnosis and Treatment of Uterine Polypi," in the *Dublin Quarterly Journal of Medical Science* for last February. From the date of the first operation to within about a month of her coming again under Dr. Kidd's care, she was completely relieved of the hæmorrhage from which she had suffered before; but the bleeding then recommenced, and was accompanied by very great pain.

On her admission, the uterus when sounded was found to measure three inches in length, about half an inch more than it normally should; and examined by the bi-manual

method, the fundus was perceived to be slightly enlarged. The co-existence of these various symptoms induced Dr. Kidd to suspect the presence of a polypus, and on the 3rd of June tents of sea-tangle were introduced, with a view to dilate the cervix, so as to allow of the interior of the uterus being explored, and the polypus removed if one were present. The next day the tents were withdrawn, and the uterus being examined, was found to have a soft polypus with a broad base growing from its fundus, a little distance from the site of the former tumour.

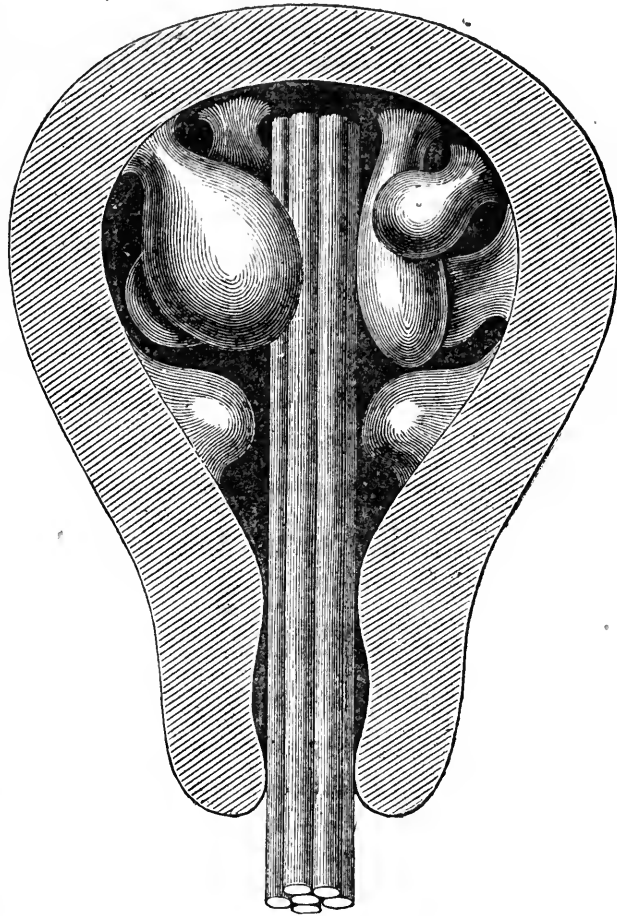

The woman having been brought under the influence of chloroform, a vulsellum was fixed in the anterior lip of the os, and the uterus having been drawn well down, the polypus was seized with a smaller vulsellum, and a noose of soft iron wire fastened to an écraseur was passed along the handle of the instrument and around the tumour; it was gradually tightened. Just when it was seized the vulsellum lost its hold on the polypus, tearing away a small piece of it. The tightening of the wire was continued gradually, however, until it severed the connection of the tumour. A small polypus forceps passed into the uterine cavity readily removed the remaining portion of the mass, which in its entirety had been somewhat larger than a filbert.

The next proceeding—namely, the application of strong nitric acid to the interior of the uterus—is one of great novelty; it was tried by Dr. Kidd for the first time in a case recorded in the before-mentioned paper, and with such good success that he conceived that in this instance, where there was evidently a disposition to recurrence of the disease, it would be desirable to destroy the growing point of the polypus. A little cotton wool steeped in the acid was pushed into the cavity and well rubbed around it; it was then withdrawn, and being saturated again, was a second time introduced; and removed as before. The os was filled with a plug of lard, in order to prevent the acid attacking the vagina, and the nurse was directed to pass an injection of warm water into the vagina in about an hour.

The woman made a rapid recovery, suffering no inconvenience from the use of the nitric acid, getting complete relief from the symptoms she had complained of, and being fit, when we saw her on the 14th of June, to leave the hospital.

The use of the sea-tangle tents in this and similar cases cannot be too highly spoken of. In his paper, which we have referred to, Dr. George H. Kidd, who originally proposed this method of using these tents for the purpose of dilating the os and cervix uteri, in a paper read before the British Medical Association in Oxford, gives a full description of the method of introducing them, and of the advantages of their employment; and on the latter point we are prepared to endorse any praise which may be given to them. They act rapidly, dilate the whole cervix equally, allow of the passage of discharges, and are peculiarly free from fetor. The want of such a substance as the tangle affords has long been felt; here, for instance, was a case in which the existence of a uterine polypus could only be guessed at, and could not have been possibly removed if the cervix had not been dilated. We have seen Dr. Kidd employ his tents in several cases, and always with entire success and satisfaction; and we feel no doubt whatever that, in the material which he proposes, obstetric surgeons will find a cheap, pleasant, and excellent substitute for the old and inefficient sponge-tents.

The position of the tents after their introduction is shown in the accompanying diagram, which represents six of them lying in a uterus containing a number of polypi. They are made by cutting an ordinary sea-tangle bougie into pieces a little longer than the uterine cavity, the measurement of which is ascertained by the sound; their ends having been carefully rounded, six or seven of them are introduced in the following manner:—The os having been exposed by the "duck-bill" speculum, its anterior lip is seized with a tenaculum, and being so fixed as many pieces of the tangle as can be readily got in are passed

through the cervix almost up to the fundus. The great point in their introduction is to avoid force, and not to press them against the fundus, because the uterus may be thus excited to expulsive action; if it shows such an inclination, a little cotton wool in the vagina will prevent the displacement of the tents. In twenty-four hours they should be removed, and this is readily done by seizing them, one at a time, with a toothed forceps, and pulling them gently away, and then the uterus having been drawn down by a vulsellum the finger may be passed right up to the fundus, and the whole cavity explored, as was done in this case.

By the will of the late Peter Maye Esq., of Portland Place, London, whose personality was proved under £350,000, he has left a contingent interest in 35,000*l.* to several charitable institutions, and by his last codicil he has made absolute the following bequests to charitable institutions—viz., Bristol Infirmary, 1,000*l.*; General Hospital at Bristol, 100*l.*; Bristol Penitentiary, 500*l.*; London Female Aid Society, 250*l.* These institutions, together with the Seamen's Hospital at Bristol, are included in the contingent bequest. All legacies are to be paid free of duty.

A PERFORMANCE of Rossini's *Stabat Mater* and J. F. Barnett's *Ancient Mariner* took place at the Hanover-square Rooms, on Wednesday last, under distinguished patronage, in aid of the funds of the Middlesex Hospital. A number of distinguished performers, both vocal and instrumental, generously gave their services, and the orchestra and choir included some two hundred performers. The excellence of the programme alone was sufficient to ensure a numerous attendance, and when it is remembered that the talented artistes were the largest contributors on the occasion, we have a right to hope that the funds of the hospital have materially profited by their exertions.

WEDNESDAY, JULY 14, 1869.

THE PURCHASE OF HOSPITALS.

THE issue which Dr. Mapother, in his recent communication to the Dublin Statistical Society on the system of appointment of hospital medical officers by purchase, as put before the public, is one which admits of no opinion alternative between entire condemnation and complete approbation; and for this reason it appears to us greatly to be regretted that the circumstances which convert the transaction of purchase from a corrupt preference of one particular candidate into an honourable selection from several equally competent have not received full expression either in Dr. Mapother's paper, or from the speakers who followed him.

Dr. Mapother declares in substance that the system of purchase causes and has caused incompetent and uneducated persons to be elected to the responsible charge of the sick in hospitals, to the exclusion of more efficient and better-informed candidates who are unable to pay the purchase money. If this assertion were true, it would without doubt have become a matter of duty for him to expose the system, and for the public to stamp it out at once and for ever. Whatever may be the personal rights and interests of medical men in hospital appointments, they cannot counterbalance by a feather weight ignorance or inefficiency on the part of the medical officer, and no considerations of hereditary or bought qualifications should be calculated at all as against the pre-eminent and absorbing necessity of obtaining the highest available degree of skill and talent for the cure of the sick poor.

We readily concede, therefore, Dr. Mapother's *sequitur*, that if his representations were correct, the action to be taken on them admits of no question; but on every other point we join issue with him, and venture to declare that he has utterly failed to show that, on the whole, the

most eligible candidate has been excluded from hospital appointments in Dublin; that in cases in which a junior or unproved candidate has been selected, the purchase system has usually been the motive power; that under any other known system of election greater purity or more satisfactory results would be secured.

The case which Dr. Mapother describes is that of electors, who, meeting apparently and openly for the selection of the best qualified candidate from many, have secretly received bribes to appoint a medical officer guiltily, knowing that he was incompetent. No such case has ever occurred in Dublin, and if Dr. Mapother's paper may be thus interpreted, we hesitate not to say that its purport is incorrect, and its substance slanderous to the profession.

The real transaction is far different. When a medical officer conceives the intention of retiring from his position, his resolve is within three days perfectly well known to every person within the earshot of medical gossip, and is generally published to the profession and the public in this and other journals. Every person who might probably be a candidate is perfectly *au courant* with the intended vacation of the appointment, the names of probable candidates, the expected date of election, the approximate sum of money to be paid, and the relative personal interests and qualifications of each candidate for the vacancy. Thus the element of secrecy, which is the first essential of a corrupt bargain, never exists except in the name. As the day of election approaches, there are, perhaps, half a dozen favourite claimants, besides half-a-dozen others who would be perfectly ready to pay the purchase money, and undertake the duties, if they thought they had the least chance of being allowed to do so.

The electors meet, and in most instances it is well known how each of them will vote. The retiring medical officer of course has his favourite candidate, but his support is hardly influenced by mercenary motives, for he is well aware that, whoever may be elected, he will receive the purchase money. Moreover, he well knows that it would be useless for him to attempt to force a second-class candidate on the electors, no matter what pecuniary advantage he might have in doing so, for each elector would have a personal profit in the efficiency, as a teacher and officer, of the incoming man, and could not be expected to lose money or prejudice the value of his appointment by joining in the election of an undesirable candidate.

Thus it is obvious that the second and most important element of a corrupt preference is eliminated from the transaction.

There is an ample choice of candidates, all of them possessing the monetary qualification, and all of them, therefore, open to as fair a competition as if they were not to purchase at all. The electors are not pecuniarily interested in any one, because it is not they who receive the money, and, therefore, the largeness of the sum cannot influence them. In point of fact, we assert, without fear of contradiction, that the amount of the consideration has nothing to say to the election, for it is well known that many candidates are never selected who would be glad to pay double the amount offered by others, but have not the concurrent *prestige* or qualities to recommend them either to the pupils, the patients, or the public.

Under this view of the subject, the corruption and nepotism out of which Dr. Mapother made so large a capital vanishes, and his hole-and-corner traffic in the right

to kill or cure hospital patients manifests itself as a perfectly legitimate open transfer of a vested interest.

We employ the phrase, "vested interest," advisedly, and on the part of the profession we maintain that an hospital appointment under the present system is a personal property.

We insist that by devoting their labour and assuming the unceasing responsibility of an hospital appointment receiving no, or, if any, an obviously inadequate public remuneration, the medical officers of hospitals do acquire a vested interest; and that until the public shall pay them sufficiently for their hospital work, it is not open to any one to interfere with the sale or purchase of that interest so long as adequate skill and attention be secured to the patients.

In the instance of the City of Dublin Hospital, and of what we may call proprietary hospitals in general, this right seems to be unchallengeable. In such cases certain persons have put down their money and formed a co-partnership or company for healing the sick. They have received no original gift from the public, nor have they ever applied a single shilling of public contribution to any other purpose than the maintenance of patients. If these persons had not come forward with their money in the first instance, the hospital would never have existed, and it seems to us as reasonable that they should enjoy the fruits of their investment as it would be that a shareholder in any railway should be at liberty to dispose of his share. The public have a right to interfere so far as to ensure effectual treatment of the sick, but no further, and any transaction which secures this desideratum is to them *ultra vires*.

And this principle has received the most authoritative recognition even where it is burdened with an objection to which the Hospital Purchase System is not open. In the Army, purchase, both within and without the regulations, is officially recognised, allowed, and fostered, and yet the promotion is accorded in this case for the money consideration and no other. In that service, if a man buys he gets his advancement as a right; there is no choice of candidates, and if he were the veriest fool or scamp, he gets his promotion in his turn as surely as he pays his money.

If this system be defensible, how shall a system which gives no peculiar influence to the money argument be condemned?

Neglecting many other arguments which have been adduced in favour of the existent system, we feel it impossible to lay down our pen without remarking on the special character of Dr. Mapother's action in the matter. With much regret we feel obliged to condemn without reserve the course he has taken. He, of all persons, ought to have appreciated the merits of the case and the effects of a misconception of it on the public mind and on the charities which, indirectly, he has attacked. Persuading him to write *con amore*, and to be thoroughly persuaded of the truth and justice of his remarks, we can hardly comprehend the force of the sense of duty which can have appeared to throw the *onus loquendi* on him. It is the obligation of every writer, and the more influential the more complete, to take every available means to neutralise prejudices or personal *pique*; and yet it seems to us that Dr. Mapother has most unadvisedly accepted the very silly and impertinent leadership of a badly-

informed journal, and has rashly, and without either obligation or reason, inflicted a severe and, perhaps, irretrievable injury on his profession, and the most valuable of our benevolent institutions.

THE WATER COMMISSION.

We have already reminded our readers that the publication of the Report of the Royal Commission on Water Supply exactly fulfils the predictions we made so long ago, and that were so rashly contradicted by the ignorant or prejudiced writers in another periodical. No wonder those gentlemen are "not satisfied" with the Report, for it demonstrates that they have all along been floundering in error, and circulating groundless statements. It is, of course, impossible to fully review the whole Report in one or two brief articles; but we cannot forego the duty of justifying what we have previously said, even though our contemporary must be thereby condemned.

Look a moment at the question of hardness. The Commission state the evidence on this point very clearly in reference to the use of the water for drinking, for culinary use, for washing and manufacturing purposes, concluding:—

"That for drinking purposes the hardness of the Thames water is quite unobjectionable, and in no way prejudicial to health. The weight of evidence seems in favour of hard water, as more free from certain dangers inherent in soft waters, on account of their greater solvent power.

"That for cooking no important objection to the Thames water has been clearly proved, except as regards the deposit in kitchen boilers, which deposit is easily removed.

"That for washing, and for manufacturing purposes generally, soft water is preferable, as more efficient and more economical; but there appears no means of expressing the amount of saving in a money estimate. Looking, however, to the fact that the hardness of the Thames water is moderate in degree, and is still further reduced by boiling, and considering also that the proportion of the whole metropolitan supply used for manufacturing purposes is exceedingly small, we cannot see that this advantage is of sufficient importance to render it necessary to go to a great distance for soft water."

The question of the action of water on lead is thus disposed of in the Report:—

"Although, under a perfectly efficient system of management, or by the substitution of iron for lead, there may be little danger to be apprehended from the use of soft water, still, under the innumerable accidental conditions which must occur in the distribution of a large town supply, arising from repairs of pipes, leakages, carelessness, peculiar states of the water resulting from local causes, and so on, there is no doubt that whilst in hard water the risk of danger is reduced to a minimum, in soft water, on the contrary, the risk must be a maximum one, and one which must always exist.

"The circumstance that generally no ill effects have been found to result from the introduction of soft water is inconclusive against the instance in which it has been affirmed; and unless a very clear and serious case were to occur, many minor cases of slight injury might take place without the cause being suspected."

But the most important point is that of organic impurity; and here the diversity of opinion has been greater than elsewhere. Drs. Letheby, Parkes, Odling, Miller, Farr, Frankland, and a number of others, were examined, and their evidence has been carefully analysed by the Commission. The conclusion, however disappointing to mere theorists, is reassuring for the public. It unequivocally condemns sensationalism, and is couched in such terms as we prophesied it would be. The magnifying of the appearances by speaking of masses of water with which no one can manipulate, is pronounced "unphilosophical," and the use of the term "previous sewage contamination" is considered unwarranted in the present condition of science. Nor does the Report stop here; for

the Commission had analyses made for themselves, and they fully confirm the conclusions arrived at by criticism of independent workers in this field of inquiry. Curiously, too, it is shown that, chemically speaking, Thames water is purer at its present source of supply than at any other part. We need not affect surprise, then, that the Commission consider the present source of water for the metropolis on the whole as satisfactory.

The Report states definitely that "when efficient measures are adopted for excluding the sewage and other pollutions from the Thames, and the Lea, and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome and of suitable quality for the metropolis."

There are many other points ably reported upon, but the consideration of which the limited space at our disposal compels us to postpone. We may close this notice by quoting the general conclusions of this Report:—

GENERAL REMARKS BY THE COMMISSION ON THE QUALITY OF THE WATER FROM THE THAMES BASIN.

"The evidence before us leads us to the conclusion that the Thames water has many good qualities which render it peculiarly suitable for the supply of the metropolis, and which give it, in some respects, a superiority over the soft waters usually obtained from the high gathering grounds. When properly filtered it is clear, bright, colourless, agreeable, and palatable, and the amount and nature of its saline constituents are considered by many to contribute to its general acceptability for drinking. It is well aerated, has good keeping qualities, and is unusually safe as regards action on lead and iron.

ON THE ORGANIC IMPURITIES.

"The evidence we have collected on this subject presents great diversities of opinion, but there is one result which, we think, is clearly deducible from the facts before us—namely, that in the present state of chemical science analysis fails to discover in properly filtered Thames water anything positively deleterious to health. Whatever may be the difference of opinion with respect to the time required for removal of all the objectionable organic matter, all the chemists agree that in Thames water taken from the present source and properly filtered all such matter has disappeared, and that the resulting compounds, such as nitrates, &c., remaining therein are innocuous and harmless.

"Having carefully considered all the information we have been able to collect, we see no evidence to lead us to believe that the water now supplied by the companies is not generally good and wholesome.

"The only point raised against the Thames water, on the ground of organic contamination, is of a less positive character; it is said that water which has been once contaminated with sewage may still contain undecomposed organic matter which, though inappreciable by the most delicate chemical tests, may still exercise prejudicial effects on the human system.

"The strongest form of this objection has reference to some opinions now prevalent, that certain forms of disease, such as cholera and typhoid fever, are propagated by germs contained in excremental matter; and it is conceived possible that when matter of this kind once gets into streams these germs may escape destruction and long preserve their dangerous character. It is said that no process is known by which such noxious material can be removed from water; and, therefore, it is argued that water which has at any time been contaminated by sewage is henceforth unsuitable for domestic use.

"These opinions have been advanced by many eminent men of science; they are worthy of respectful attention, and ought to operate as a constant stimulus to the most searching examination of the state of the water, to the improvement of the modes and means of scientific analysis, and to the diligent collection of medical data as to the effect of the waters upon the public health. But we cannot admit them as sufficiently well-established to form any conclusive argument for abandoning an otherwise unobjectionable source of water supply.

"We may also expect that the state of the Thames and the Lea will be very much improved by the exclusion from them of all sewage and other offensive matter, in accordance with the provisions of the Acts of 1866 and 1868. And it is

worthy of consideration whether these provisions should not be extended higher up the tributary streams, so as to exclude all possible sources of noxious pollution.

"We are of opinion that when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and the Lea and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome, and of suitable quality for the supply of the metropolis.

"The analyses made specially for us of the waters in the various parts of the Thames basin are, we conceive, of great interest and value, and will be very useful as data for comparisons of the state of the river at future times. The result shown by them that the present point of intake is the best that could be chosen in the whole course of the river is peculiarly important and satisfactory."

As to filtration, no one questions its value. It was made compulsory by the Act of 1852, but the evidence shows that it has been very imperfectly performed. The Commission say:—

"There seem to be no efficient means of enforcing an observance of this provision of the Act, and the neglect of the companies to comply with it, notwithstanding the repeated attention drawn to the imperfect filtration, shows the necessity for some change in the system of supervision to which the supply of the metropolis is subjected."

THE MEDICAL COUNCIL.

THE huge mountain has accomplished the destiny to which it is brought at regular recurring periods of twelve calendar months. Another litter of ridiculous mice appears in the medico-political world. The progeny are all weakly, and will scarcely live long, while the progenitor itself is in imminent danger. We turn from metaphor to give expectant readers a summary of what has been actually done.

First day.—New member took his seat. President delivered address—the one substantial contribution of the session.

Letter from Mr. Simon (on behalf of Privy Council) read.

Letter from Dr. Struthers (on behalf of Garioch Association) read.

Letter from Dr. Prosser James read.

Letter from Dr. Bell Fletcher read, and deputation from Birmingham agreed to be received.

Reduction of printing expenses (much needed) resolved upon.

List of satisfactory preliminary examinations agreed to. Reports of Branch Councils submitted.

Second day.—Dr. Andrew Wood attacked Sir John Gray, M.P., for his recent speech in the House of Commons. Sir D. Corrigan defended his absent friend.

The usual squabble about the Queen's University took place, with the usual exchange of compliments.

The letters read on first day were referred to a committee to report.

Third day.—Second report of committee on State medicine presented.

A petition of Lothians Association referred to committee.

Returns of examinations for public services presented.

Fourth day.—Report on preliminary examinations, and on Queen's University examinations, presented.

John Pattison struck off Register.

A communication on vaccination from College of Surgeons, and another on education, from Medical Teachers' Association received.

L. A. La'Mert struck off Register.

G. M. Bernard restored to Register, his name having been removed through a false report of his death.

Fifth day.—Letters from McGill University and British Medical Association read.

Danish Pharmacopœia accepted with thanks.

Letter from Edinburgh College of Surgeons read.

Letter from Dr. Philip Maclagan (on lunacy certificates) read.

Sixth day.—Solicitor reported that La 'Mert's name could not be erased this session.

In reply to Dr. Alexander Wood, President stated Home Office had not inquired of him as to Sir John Gray's question in the House of Commons.

Dr. Bell Fletcher, Messrs. Sampson Gangee, Oakes, and Owen received as a deputation from Birmingham.

A long time were the deputation waiting while Councillors talked about how to receive it. An ingenious gentleman among the reporters calculated that about eighty guineas was thus spent—a price rather high to pay for the whole work of the session.

Mr. Gangee spoke with great force. How the Councillors must have envied that gentleman his power of speaking, briefly and to the point!

More about State medicine.

Seventh day.—Committees.

Eighth day.—State medicine and Committees.

Dr. Burrows, alas! resigned the Presidency. We ne'er shall look upon his like again.

Resolved into Committee; reopened at a later hour.

Dr. Paget, the able representative of Cambridge University, elected President. Is that body to have another representative, or the Council to diminish its number by one?

Ninth day.—Appointment of Committees.

Report of Finance Committee carried.

The *glorious* result is "an estimated excess of expenditure over income of £375." Unhappy profession! so much talk! so little work! so much expense!

Report of Committee on Education read, and a huge volume of appendices laid on table. It is well the resolution to diminish printing expenses was adopted. Resolved to circulate this huge book, and postpone action for the present year.

Tenth day, Monday, July 12.—Report of Committee on

Amendment of Medical Acts, to which all the documents had been referred. A vote for the *status quo*—an expression of self-satisfaction—an undisguised attempt to smother the documents alluded to, and ignore the dissatisfaction of the profession with the constitution of the Council.

Sir D. Corrigan proposed to try to obtain a Royal Commission to inquire. Not accepted.

Dr. Andrew Wood again brought forward his proposed direct representation.

Dr. Alexander Wood wisely refused to embark in such inquiries the last day.

The other documents were burked, and the remainder of the sitting was an illustration of "how not to do it."

SCOTLAND.

THE CHAIR OF CLINICAL SURGERY AND THE UNIVERSITY OF EDINBURGH.

THERE is no subject of professional conversation that is just now so interesting as to who shall succeed Professor Syme in the Professorship of Clinical Surgery. Dr. Patrick Heron Watson, Mr. Spence, Dr. Joseph Bell, and Mr. Lister, of Glasgow, are all put forward by their friends, and in some instances requisitions, numerous signed, have been presented. No one is likely to doubt the competence of either of these gentlemen for the post. Mr. Lister is a graduate of the London University and F.R.S., and his friends are very active on his behalf, and put forth his researches in the antiseptic principle as one of the greatest surgical triumphs of the day. He, however, holds the professorship at Glasgow, and might possibly not care to leave it. Dr. Bell is an Edinburgh graduate, and, besides his position as a teacher of surgery, has been President of the Royal Medical and of the Medico-

Chirurgical Societies. Mr. Spence's position is as peculiar as it is high. Whether he take the clinical chair or not, we should gladly see the chair he now so well fills recognised as one demanding clinical wards for illustration.

Dr. Watson's career is so distinguished, that the profession in the three kingdoms would gladly see it crowned with the object of his ambition. Lecturer on Surgery at the College of Surgeons, Examiner at the University of St. Andrew's as well as his college, Surgeon to the Infirmary, the Lock Hospital, the Eye Infirmary, and other institutions, he has diligently used his opportunities, as witnessed by his many contributions to practical surgical literature. He is an Edinburgh graduate and F.R.S., and has been a successful surgical teacher in Edinburgh since 1856. He has served his country as staff assistant-surgeon in the Crimea, and obtained the Crimean and Turkish medals and clasps. His experience has thus enabled him to deliver the courses on military surgery in addition to those on general and on special surgery and pathology, and he has thus instructed more than 1,100 pupils. The list of his writings numbers 33, and his communications to the Medico-Chirurgical Society no less than 97. Some of these are of the very greatest interest. We do not intend to enumerate them, but it would be unjust not to call the attention of our readers to the great practical value of Dr. Watson's contributions on excision of the knee joint. His work on this one subject places him in the front rank of surgeons, while his labours incidental to it, as in excision of other joints, would be enough to make the reputation of one who had done no more. In addition, there are few subjects of practical surgery that have not received illustration from his pen. A gentleman of such energy would not fail to work hard in the new appointment for which he is a candidate. The appointment is made by the Home Secretary, who will, no doubt, carefully weigh the claims of all candidates.

Notes on Current Topics.

Our "Trumpeting" Contemporary.

WE regret to have again to return to the subject of the immense amount of "trumpeting" required to get rid of the copies of the medical journal that has written so disparagingly of "trumpeting" by medical authors. The *Lancet* so thoroughly appreciates the probability of getting a sale by "trumpeting" in the *Times* that it has again put forth eleven distinct advertisements in that newspaper for Saturday last, although it has not withdrawn the offensive charges against Dr. Fuller for his preferring the *Times* as a medium for advertising his books to the columns of the *Lancet*. This last journal proves by its conduct how much it values the *Times* as a medium for "trumpeting" itself. It also constantly exhibits a peculiar sensitiveness to the opinions of the *Times*. As it has long made a practice of indulging in gross personalities, we beg to quote the *Times* respecting such conduct. *Appropos* of the Murray-Carington squabble, the *Times* said:—

"When a journal seeks to attract readers by the grossly personal nature of its attacks upon individuals, whatever calls attention to these attacks is a distinct boon to it. Its hopes of commercial success are based upon the calculation that out of a large proportion of readers there will always be a certain number who like personality for its own sake. Among Americans, unless their Press is cruelly libelled, there are several such journals, and so it was in England some thirty or forty years ago. An immense improvement has since been made, and no journal of respectability, however humble its position and limited its circulation, would now think of venturing upon the personalities which were then common even with journals of high mark. This ini-

provement has been so steady and so general that there was reason to hope the taste for journalistic personalities had altogether died out, or, at any rate, survived only in so faint a form that no man would conceive the idea of making a paper pay by appealing to it. It is with great regret, therefore, we have noticed even such faint reaction from this improved tone as that denoted by the scene which occurred the other night in St. James's-street, and which represents a type familiar enough in the last generation, but unknown, as we had fondly deemed, to this. For though no man of sense can consider the course which Lord Carington took justifiable under any circumstances, there were many who fully sympathised with his indignation at the grossly scurrilous attack made upon his father, and who, sharing his mistake as to the authorship, were by no means sorry that personal chastisement should have been inflicted upon the person whom they believed to be guilty. Indeed, the whole affair is just such an one as might have occurred in the days of the *Satirist*, except that public indignation was, happily, more prompt to visit the supposed writer of the offensive article."

We particularly commend this to our contemporary, and hope, though it is too obdurate to confess its transgressions, it will from this time cease its vain attempts to court popularity and acquire power by malignant personalities. If not, the time may come when some event shall justify a resort to such means as are alluded to in the following paragraph from the same article in the *Times* :—

"It is in the power of the Clubs to exert a social influence in such matters, and to make it understood that a man known to be connected with a grossly scurrilous paper is not fit for the society of gentlemen. Much as we regret the occurrence of this brawl, we shall not, when we consider the causes which led to it, consider it an un-mixed evil if it is the means of calling forth from the Conservative Club an expression of opinion that no one who had written the article which provoked the brawl is fit to be received upon equal terms by any society of gentlemen."

The Ophthalmic Cacoethes Scribendi.

THE ophthalmological revival, which has so severely taken the profession of late years, perhaps wafted, like the pleuro-pneumonia, from Germany, has resulted, it would appear, in a critical flux, which has left the patient in a condition of melancholy debility. We read in one important American medical periodical that Brother Jonathan has escaped the attack, on which we congratulate him, though it seems to be a matter of regret across the Atlantic that he has not "put it over him."

It appears, as the result of "the experience and opinions of the leading publishers, importers, and authorities" on medical books in New York, that out of 6,000 books and pamphlets of medical subjects published within the last ten years in Europe, ophthalmology absorbed no less than 1,500, or 1 out of 3; on the other hand, obstetrics, and all its allied subjects, only produced 500; and the entire domain of medicine and surgery only 4,000.

The practical result of this enormous discharge of *flatus* is that the patient is now quiescent, and probably 1,200 out of the 1,500 authors have made themselves ridiculous.

THE Right Hon. G. J. Goschen will preside at the distribution of prizes of the London Hospital Medical College on the 19th inst., at 2 p.m.

THE St. Andrew's Graduates' Association take an excursion to St. Alban's on the 20th inst.

WEEKLY returns of mortality in Paris have been officially commenced. The first return has been supplied to, and forms a paragraph in the last return of our own Registrar-General.

DR. W. SANDERS and Dr. Grainger Stewart are candidates for the chair of pathology at Edinburgh University.

DR. RUTHERFORD has been appointed to the chair of Physiology at King's College.

SEVERAL gentlemen are candidates for the Assistant-Surgeony at the Westminster Hospital.

IN the new number of the *Westminster Review* there is an important article on "Prostitution in relation to the National Health." Considering the extent to which the subject of prostitution has lately been discussed in our columns, our readers, whatever their opinions, will probably turn to that article with unusual interest.

MEETING OF THE GENERAL MEDICAL COUNCIL.

(Continued from page 18.)

MONDAY, JULY 5.

ON a motion being made by Dr. STORRER, seconded by Dr. EMBLETON, that a letter from the Medical Registrar of Trinity College, Dublin, be placed on the Minutes, Dr. APJOHN made the following remarks :—

I think, Sir, I may be permitted to interpose in relation to the question about to be put. This letter of Dr. Haughton's is a letter addressed by him to our President as an individual, and certainly without having got the permission or the direction of the Board to forward any such document. If, therefore, such a letter as this be published, a precedent will be made which may lead to very inconvenient consequences. The letter in question seems to be considered by the members of Council in the light of an attack upon the governing body of the University. I would ask, is it the intention of this Council to co-operate in such an attack? I think it will, on reflection, pause before it embarks in such a course. The individual most directly assailed in this letter is a man of great and varied attainments; and one highly esteemed and respected in the University. This gentleman, it appears, has committed the mistake of saying that a common cement was made in the School of Physic of Clinical Examination in Medicine; whereas he should have said in Surgery. But is there any person here who will venture to assert that he intended to mislead the Council? or will any body assert that it is a matter of any importance whether this first step was taken in Surgery or in Medicine? I entreat the Council not to take any side on this question, and not to assist in giving publicity and consequence to what I cannot but consider as a document of a highly indiscreet and unjustifiable nature. I would again remind the Council that this is a letter not from the Dublin University, but from Dr. Haughton in his individual capacity, and that we cannot, by putting it on our Minutes, assist in an object of which many of us strongly disapprove.

TUESDAY, JULY 6.

The first business of importance brought before the Council was the reception of a lengthy communication from the College of Surgeons of Edinburgh, commenting on the proceedings of the Council during the past Session. On a motion to insert the communication on the Minutes, a very animated discussion took place as to the desirability of encouraging the different licensing bodies to criticise the proceedings of the Council. Upon the vote being taken as to the communication being inserted upon the Minutes, the majority were against its admission.

A letter was read from Dr. MacLagan, on the subject of lunacy certificates, when the Council determined that a communication be made to the Home Secretary in reference to the present state of the law on that subject.

The conduct of the Queen's University in Ireland, in reference to preliminary examinations, formed the subject of discussion during the remainder of the sitting.

Dr. PARKES moved, and Dr. EMBLETON seconded, "That the Registrar be requested to write to the Secretary of the Queen's University in Ireland, asking for the Report of the Committee of the Queen's University, to which the Report of the Committee of the Medical Council on the Visitations of Examinations was referred, and if the reply be that the Committee has not reported, that the Registrar be instructed to write and inquire for a definite reply to the passage in the Report of the Committee on the Visitation of Examinations which referred to the Preliminary Examination of the Queen's University."

To this an amendment was moved by Dr. STORRAR, and seconded by Dr. BENNETT,—"That this Council, having issued recommendations to the bodies enumerated in Schedule A of the Medical Act (viz., 'That no medical student shall be registered until he has passed a preliminary education, as required by the General Medical Council; ' and 'That no licence be obtained at an earlier period than after the expiration of forty-eight months subsequent to the registration of the candidate as a medical student'), and this Council having learned that the regulations and practice of the Queen's University in Ireland are not in accordance with these recommendations, the Council request the attention of the Queen's University to this want of accordance, and express the hope that before the next annual meeting of the Council the University may be able to announce to them that their regulations and practice are in conformity with the aforesaid recommendations, and thereby avoid the necessity of a representation being made by the Council on this subject to Her Majesty's Most Honourable Privy Council, under the 20th section of the Medical Act."

The discussion upon this subject had not concluded when the Council adjourned.

WEDNESDAY, JULY 7.

The adjourned discussion on the subject of the Queen's University was resumed, and it ended in the rejection of Dr. Storrar's amendment, and the adoption of Dr. Parkes' motion, as stated in yesterday's proceedings.

The Council then received a deputation by appointment, together with a memorial signed by upwards of 5,000 practitioners, with regard to various suggested amendments of the Medical Act. The deputation consisted of Dr. Bell Fletcher, Mr. Sampson Gamegee, Mr. Arthur Oakes, and Mr. D. C. S. Owen. Several questions were asked by different members of the Council, and answered by the deputation, who were informed by the President that the memorial would receive the fullest consideration.

The subject of State Medicine was brought forward by Dr. ACLAND, who proposed, "That in any amended Medical Bill which may be prepared for Parliament by the Council it is desirable that the requisite permissive clauses for providing a qualification in State Medicine be inserted." Dr. Christison seconded the motion, which was supported by Dr. Macrobin, Dr. Alex. Wood, Dr. Stokes, Dr. Aquilla Smith, and Dr. Storrar, and opposed by Dr. Andrew Wood. The debate was adjourned at the rising of the Council.

THURSDAY, JULY 8.

The Council resumed its sittings at 2 o'clock as usual, when, after the minutes of the previous day had been read and confirmed, the Council, on the motion of Dr. Andrew Wood, Chairman of the Business Committee, suspended its sittings with a view of expediting the business of the Session, resolving itself into the following committees:—

- On the Amendments of the Medical Acts ;
- On Preliminary Education ;
- On the Pharmacopœia ; and
- On Communications from Dr. John Harley, Mr. Courtauld, Dr. MacLoughlin, and Dr. Edwards Crisp.

FRIDAY, JULY 9.

The Council resumed the adjourned consideration of the Report of the Committee on State Medicine.

Dr. RUMSKY believed that some of the misconceptions which had arisen in the Council from defect of information respecting the report and proposals of the State Medicine Committee might have been averted had it been possible for that Committee to comply with the second resolution on this subject, passed by the Council on June 27, 1868 :

"That the Committee send in their Report so soon as it may

be ready, to the Executive Committee, and that the Executive Committee have power to print and circulate the Report among the Members of Council prior to their next Session." Had the Committee been able to place their Report, with the Appendix, in the hands of members a few days before this session commenced, some part of the debate on Wednesday last might have been spared, with benefit to the Council. Moreover, he was of opinion it would have been better had the first Report of this Committee, which contained resolutions adopted by the Council in the last Session, been carefully examined by members.

Those resolutions, at least the most important of them, were indeed given, in substance, in the letter which our Chairman addressed to many persons of distinction, within a month after the Session, thus:—

"The Committee have decided that such diplomas or certificates ought to be granted after due examination to persons who are already, or shall hereafter be entered upon the *Medical Register*, and to no others."

The resolutions had also been more recently summarised by himself in these words (at p. 81 of the Appendix):—

"Under the term 'State Medicine' the Committee included Legal Medicine or Medical Jurisprudence, and Preventive Medicine or Public Hygiene.

"They resolved unanimously that it was desirable that special certificates or diplomas should be granted for knowledge of State Medicine;—that the proposed qualification should not be compulsory on all registered practitioners;—that no one should be allowed to register a qualification in State medicine unless he had previously obtained a qualification entitling him to be on the *Medical Register*;—and that the possessor of the proposed certificate or diploma should be entitled to register it as an additional qualification."

These resolutions had also been read to the Council in detail by Dr. Stokes, which showed that the Committee at once admitted the known fact that a public demand existed for a new and distinct qualification in State Medicine, which they believed the Medical Council was called upon to supply. They also showed that the Committee felt bound to suggest a mode of supplying that demand, and acknowledged from the first that the necessities of the public service could be met only by requiring of candidates for certain medical offices and employment a qualification, certifying to a course of study and preparation whom it would be utterly in vain to attempt to include in the general minimum qualification required of all registered practitioners. The Committee saw plainly, what he trusted this Council would admit, that however the education of all future registered practitioners might be improved in this direction, by better elementary teaching and better methods of study—*ex. gr.*, in the physical sciences, in physiology, in etiology, in the therapeuticals of toxicology, and in the first principles of hygiene—there lay beyond all this a wide field of study and practical instruction to be cultivated, and its cultivation to be verified by a special certificate.

The Committee saw that this special qualification and these high acquirements could not possibly be imposed on all students without interfering dangerously with studies, universally acknowledged to be of primary and paramount importance in practical medicine and surgery, and which must be pursued within that curriculum of four years which we require of all medical students.

It had been said that the Committee had decided and prejudged the whole question beforehand. His reply was that it had only admitted a principle, without prejudging any of its details. The Corporation which Dr. Andrew Wood represented had prejudged the question in denying the necessity for any measure of the kind. And he maintained that the Committee merely exercised ordinary prudence and foresight in perceiving—what, he regretted to find, all did not yet perceive—that the present necessities of public medicine were to be met only by fresh legislation. But he denied that, by taking a timely step, they were attempting to force any final measure upon the Council. The Committee asked only for a permissive enactment which might enable the Council ultimately to register, as a distinct and additional qualification, those certificates or diplomas of proficiency in this department of medicine which may be granted by the Universities of the Kingdom, or possibly by other Boards. To postpone a provision for the requisite clause or clauses until after another session would be virtually to invite defeat. For, if the Government should take up the Amendment Bill and pass it minus the proposed permissive clause, the opportunity for legislation of this kind would probably be past.

If proof were required that there existed a public demand for such a measure, he could produce evidence which he thought could not fail to convince the Council. To take at least one branch of State medicine, that relating to the public health, he presumed no one would question the necessity for appointing highly qualified officers of health all over the kingdom. No one would venture to question it if they knew the facts which sanitary reformers had been long accumulating and which were now being produced before the Royal Sanitary Commission. Yet, when those who were working the question, as some of them had worked it, applied to Government or to the heads or advisers of Government departments to organize such a staff, they answered, "True, the thing ought to be done; but where are the men? We cannot insist upon a general appointment of a scientific and specially qualified staff until we know that there is a sufficient number of persons so qualified to complete the organization."

This was the substance of a reply which he had more than once received; it might have been expressed in terms terse enough, but not always flattering to the profession. Would the Council, then, consent to lie longer under the imputation? Should they, by declining to aid in the education and preparation of a sanitary staff, afford the Legislature an excuse for inaction? Would they repudiate what he ventured to call "our public liabilities?" Or postpone this question from year to year until the Government took the matter into its own hands and settled it in its own way, and thus set aside this Council? Of course, if the Council should so please, he would say, "*Fiat justitia, ruat hoc cœlūm.*"

There were two public documents showing the opinions of the most distinguished men in this country—men, he believed, who were not surpassed in Europe for their mastery of this subject.

The one entitled "An Instructional Minute relative to the Duties and Qualifications of Officers of Health, &c., &c." This was issued so long ago as 1855, and was drawn up by Mr. Simon, F. R. S., in which he remarked, "The most distinguished practitioner of a neighbourhood may indeed happen to be also the person best qualified for a sanitary appointment; but the reverse must often be the case, for not all members of the medical profession can afford equal leisure to cultivate those distinctive studies; and it will imply no disparagement of men actively and skilfully engaged in the treatment of disease if the special qualification in question should sometimes be found in other members of their profession rather than in them. . . . The branches of knowledge here spoken of are not the parts which have the most direct relation to the treatment of disease."

The other document to which he referred was in the 27th Annual Report of the Registrar-General, containing a most important letter from Dr. Farr, who proposed the general appointment of Registration Medical Officers—men who would be primarily employed in statistical and medico-legal duties, but who would ultimately become the chief sanitary consultants of the districts—who would in fact be officers of health.

He begged also to direct attention to resolutions "passed by the National Association for Promotion of Social Science" last year in Birmingham, in favour of the appointing of these medical officers of health and registration throughout the kingdom.

The third resolution states, "that the education, qualification, and tenure of office of health officers should be such as to guarantee efficient and beneficial action."

He would ask, were these regulations respecting the education and qualification of public medical officers to be made under the authority of the Council or by the heads of Government departments? He thought the decision gravely affected the honour of the position of this Council. In this matter the eyes of Europe were upon us. He supposed that there was no one who as a scholar, as a promoter of education in all departments, and as a member of Parliament interested in these questions, stood higher than Lord Lyttelton. Any one who had as he had, the gratification of hearing his address at Birmingham in 1868, would acknowledge how thoroughly he grappled with the question of education, not so much for the masses as for the classes, and for the various purposes of civilization and pursuits of life.

The Council was being watched by persons of influence who would not fail to notice what they considered to be derelictions of duty.

Then what were the authorities opposed to this movement? There was the College of Surgeons of Edinburgh; there were also the opinions of Dr. Maclagan quoted by Dr. Andrew

Wood on Wednesday with much approval. Considering that this document (the Appendix to our Report) had then been only just tabled, and that members had had scarcely an opportunity of examining its contents, it gave him additional proof, if he wanted any, of Dr. Andrew Wood's great acumen and readiness in discovering at once, and unearthing from such a mass of evidence, the only opinion which it contained on his side of the question. He told us nothing of the recommendations of twenty or thirty other gentlemen, some not a whit less distinguished than Dr. Maclagan, and all in favour, more or less, of the project. See what Dr. Alfred Taylor, the chief authority in Medical Jurisprudence we have, says about it; what Professor Rainy and Travers advance, [to some extent, in its support; what men actively engaged in practical work, as Dr. Mappother, of Dublin, and Surgeon Hewlett, Coroner and Health Officer for Bombay, so fully recommend; what learned men abroad, as Dr. Pappenheim, of Westphalia, advise with great minuteness as to this special qualification. Above all, hear what Professor Pettenhofer says of the project:—"Your plan of the reform of medical instruction in the interest of the public sanitary measures and police regulations is in accordance with the spirit of the age, and is as thorough as comprehensive. I am envious that England should so far outstep my German fatherland in this matter."

He (Dr. R.) would not occupy longer the time of the Council, but conclude by observing that prompt action in the matter would redound greatly to the honour and credit of the Council, increase its influence with the Government, and enhance its reputation throughout the world.

Mr. HARGRAVE said he objected to the motion on several grounds, but chiefly because the Committee had not favoured the licensing bodies, the members of the Council, and others interested, with the Report as promised, they had not therefore had time or opportunity for giving the matter that consideration to which it was entitled. Since the Report had been placed in his hands, he could detect little but vague recommendations, and ideas so confused and conflicting, that he could not possibly give his adhesion to it. Some advised that the time requisite for proficiency in those branches relating to State medicine should be six months, others two years. He begged to remark that if, instead of passing such imperfect recommendations, each College appointed a Professor of Hygiene, as did the Royal College of Surgeons in Ireland,—which body, he was compelled to say, was far ahead of other Educational Corporations in this respect—it would obtain the object now sought by this permissive clause, with this advantage, that it gave the necessary instruction without any special licence or degree. These lectures, delivered by Professor Cameron at the Royal College of Surgeons in Dublin, had been patronised most extensively by all classes, and with the greatest success. He might further state that there was at the present time a graduate in the University of Oxford, who was preparing himself for discharging the duties relative to such an appointment.

Dr. RISDON BENNETT thought that at the present advanced stage of the Session, it was desirable to keep to the terms of the motion before them. Whilst admitting that the subject was a most important one, he doubted if it were possible to give it the attention which was due to a measure of such magnitude, during the present Session. Much valuable time and attention had been bestowed upon the question of State medicine, by the Committee who drew up the Report; but the rest of the Council and the Licensing Boards had not had the opportunity of considering the matter. Although himself of the opinion that some kind of diploma should be given to those who by careful study attained to a satisfactory proficiency in State medicine, as a qualification for the office of a State medical officer, the question nevertheless resolved itself into this, supposing a door were opened for the introduction of special qualifications as grounds for admission to the Register, whether many other demands would not necessarily follow. There was a disposition abroad already, to force the Council to admit a knowledge of midwifery, as a qualification for this admission, and on these grounds he deemed it more prudent to postpone legislation upon the question during the present Session. He did not want to throw cold water upon any one desirous of studying State medicine, on the contrary. But he strongly objected that any new qualification should be placed upon the Medical Register.

Dr. FLEMING remarked that if it were true "That in the multitude of councillors there was wisdom," it was also true, "That in the multitude of opinions there must be confusion." He thought the Council were going too fast in taking up the matter as it had done. He admitted and hoped that something

would be done, but he would greatly prefer that the Universities and not the Council should deal with the question, and that they should have power to grant certificates for proficiency in this branch of study.

Dr. QUAIN agreed with Dr. Fleming that the Council was going too fast. If they turned to the motion before them they would observe that the words "*it is desirable*" were placed in italics, and really meant that the Council was pledged to something; and what was the pledge? clearly to institute a doctorate in State medicine. He strongly objected to this, being confident that if the door were open, there would soon be a formidable list of claimants for admission to the Register on special qualifications. He thought, moreover, the wording of the motion was very obscure, and that under it lay a good deal the Council ought to know. He could not help stating that the correspondence throughout the Report was contradictory, and quoted several opinions therefrom which fully justified the observation he felt bound to make upon it. He (Dr. Quain) would ask the Council where it would stop, if it sanctioned the admission of a single qualification as that for which a place was now sought upon the *Medical Register*. He had no objection to the examining bodies giving a certificate or diploma of special proficiency in State medicine, but he did object to this Council giving the sanction of its authority to this or any other specialty; and he concluded by reading an amendment which he intended to propose at the proper moment:—

"That the Council, whilst expressing their entire approval of an improved education in State medicine, and of a definite recognition of the attainment of individuals in the subject by certificates of special proficiency or otherwise, recommend that the Report and Appendix be forwarded to the Licensing Bodies, with a request that they would favour the Council with their opinions on the following points:—

1. "The facilities that might be afforded for extending and improving the education of persons wishing to study the subjects comprised in this Report.

"2. As to the desirability of granting the certificates of special proficiency in any or all of these subjects.

"3. As to the desirability of granting a special degree or diploma in this subject."

After a few remarks from Mr. Cooper, Dr. Embleton, and Dr. Macrobin,

Dr. SMITH said he approved of the motion of Dr. Acland, because it was conditional. It would be of great advantage in any future Medical Act that such a clause should be inserted, as it rested entirely upon a contingency.

Dr. SHARPEY thought that there was considerable misapprehension as to the objects of this clause. The Council were only asked that means should be taken whereby well-educated medical men should be encouraged to pursue such a course in addition to their ordinary studies. He was against any special qualification being granted for the registration of a degree for this purpose; and it therefore resolved itself into a question of the shape the Committee were prepared to recommend, and if it proposed to provide for this by some special Act, or simply to ask the Council to place the qualification upon the Register.

Mr. HAWKINS had some difficulty in making up his mind as to which way he should vote. He quite agreed that any man who had studied this special subject would be better qualified to fill the post of Medical Officer of Health than one who had not gone beyond the prescribed bounds of the curriculum; still he objected to any special qualification being granted for the purpose.

Dr. ALLEN THOMSON said it could not be denied that the Council were unanimous that the question had now assumed such a shape as to necessitate something being done either now or at some future time. If the amendment of Dr. Wood were accepted, it would again throw aside the question until next session, and to this he strongly objected.

Dr. ACLAND said, as Chairman of the Committee on State Medicine, he had every reason to feel grateful that such an amount of time and attention had been bestowed upon the consideration of the Report. He knew the Council were much divided upon the question under discussion, both as to the time and the manner such a measure had been brought forward; others were of opinion that the plan was not at all necessary. Of the first he could only say, that now was the time, unless the Council abrogated its functions altogether. The opinions of University professors was this. If the Medical Council will give us the cue, if it can be shown that by the adoption of such recommendations we shall be doing a

national duty, we will do it. The Committee, had, therefore, determined that now was the right time, and he was of opinion that the permissive clause moved by him would supply every requirement. He objected that it should be thought the Committee had not made up its mind; it had now done so, and he strongly deprecated the desire that they should wait another twelve months before coming to a decision upon the point.

In explanation to some inquiries, Dr. Acland said that it was not sought that this measure, if carried, should become a loophole to the admission of unqualified men upon the Register. He thought he had distinctly stated that it was to be an additional qualification for those who were already upon the Register.

Dr. STOKES said the Council met year after year at great expense. The present was not the first time the matter had been brought forward; an abundance of time and attention had already been bestowed upon the matter, and he considered the present a most opportune time for showing the profession that they were anxious to do all in their power to further such improvements as were deemed necessary in every branch of medical education. He trusted, therefore, the question would be decided at once and without another postponement.

Mr. HAWKINS then moved the addition of the following words to the resolution before the Council, "In addition to any qualification sanctioned by the Medical Act."

The following amendment, moved by Dr. ANDREW WOOD, and seconded by Mr. HARGRAVE, was then put from the chair and lost by 13 to 9:—

"That the Council come to no decision in the present session as to the desirability of inserting in any amended Medical Bill permissive clauses for registering a qualification in State medicine, but that the matter be delayed till next session; and that during the recess the Report of the Committee on State medicine, with the evidence appended, be transmitted to the licensing bodies for their consideration."

Two other amendments, one by Dr. QUAIN, the other by Dr. THOMSON, were next read, both sharing a like fate—the numbers for and against being the same as in the preceding amendment.

The original motion by Dr. ACLAND, seconded by Dr. CHRISTISON,

"That in any amended Medical Bill which may be prepared for Parliament by the Council, it is desirable that the requisite permissive clauses for registering a qualification in State medicine be inserted," with the additional words suggested by Mr. Hawkins, was then put from the chair and carried:—

The PRESIDENT here rose and said:—

GENTLEMEN,—Before quitting this chair, which I have occupied for so many years, I would wish to say a few words. Last year you did me the extreme honour to reelect me as your President. That distinction I accepted with the reservation that I could not agree to occupy the chair for the usual term of five years, but that I would do so for the present session, or so long as the Council should deem it desirable for the accomplishment of some of the important reforms which had already been begun. Some little misapprehensions have existed on this point, but I need not now go into details, because this was already explained at the beginning of the present session. There are private reasons which necessitated me to wish to resign my seat last year—reasons which are already known to many members of the Council, and which I refrain from mentioning publicly, lest I should be considered egotistical. Those private reasons still exist, and there are also public reasons why I should decline to fill the Presidential chair any longer. I do not think myself that when any man has had the good fortune to occupy such a distinguished post for six years, that he should continue to hold the office, so as to lead any one to imagine that he holds it simply for personal glorification or interest. By your great favour I have been raised to the distinguished position of President of the Medical Council; but I do not see why I should stand in the way of other men who are as good or better than myself attaining that distinction. It is on that ground that I am averse to continue still to occupy the chair. When I resigned last year, I expressed my thanks to the officials and members of the Council for the great aid given me. I renew those thanks for their assistance during the past year. But last year I felt there was an omission, which omission before I leave to-day I am anxious to supply. It is in refe-

rence to the public press, and more especially to those gentlemen who sit at that table, the reporters of the press. I cannot retire from this chair without expressing my admiration of the accuracy, fidelity, and impartiality of their reports. I cannot help also expressing my gratification at the extreme prudence, tact, and circumspection with which the conductors of the medical journals have adverted to proceedings which have sometimes taken place in this Council. I hope in leaving you I leave a fair name behind, and trust you will condole and make allowances for any shortcomings which you may have observed in my performance of the duties which devolved upon me—duties which, on many occasions, have been responsible, arduous, and painful. I thank every member of the Council for having assisted me in maintaining order; and I hope that, after conferring among yourselves, you will arrive at a unanimous conclusion as to my successor. With these few remarks I bid you all farewell.

The PRESIDENT then retired, amidst the most profound and respectful silence.

On the motion of Dr. ANDREW WOOD, Dr. Spokes took the chair, *pro tem*.

Mr. HAWKINS rose to express his great admiration for the able and impartial performance of those duties which had devolved upon their late President. He knew he but echoed the feelings of the whole Council, in adding so small a tribute to one who had done so much to reconcile the conflicting opinions of the profession, and to promote the harmony and business of the Council. He would, therefore, move—

“That the warmest thanks of this Council be given to the late President for the able and admirable manner in which he has so long conducted the business of the Council; for the kindness and impartiality which he has uniformly displayed towards the Members of the Council, and the determination he has shown on all occasions to conduct their discussions with the view to the improvement of the Education of the Medical Profession and the welfare of the public; and that this motion be communicated to the late President.”

Dr. CHRISTISON seconded the vote of thanks, adding that no words of his were necessary to recommend a resolution which must be cordially acquiesced in by every member who had had the good fortune to sit at that table.

The motion was carried by acclamation, and the reporters were requested to withdraw.

The Council then deliberated in private for about an hour as upon whom the choice of President should fall. When the reporters were readmitted,

Dr. ACLAND proposed, and Mr. COOPER seconded, that Mr. Caesar Hawkins, who, from his previous history, knowledge of the profession, and of all the questions likely to come before the Council, was peculiarly fitted for the office of President.

Dr. AQUILLA SMITH proposed, and Sir DOMINIC CORRIGAN seconded, that the representative of the University of Cambridge, Dr. Paget, be elected President.

The vote was then taken, and carried in favour of Dr. Paget.

Dr. Paget and Mr. Caesar Hawkins were then sent for, and Dr. Stokes (chairman) formally declared Dr. Paget elected as President of the Medical Council for the space of five years.

Dr. PAGET, the President elect, who when called to the chair was visibly affected, said:—Gentlemen, I hardly know what to say, or how to thank you, for the honour you have bestowed on me. I do thank you from my heart. It is an honour to which I could never have aspired, or even thought of aspiring. When I look round this table, and see those whom I have held in honour—I should more truly say reverence,—ever since I had any acquaintance with medical science; and those, too, whom I have known since I became a member of the Council, and whose capacity for business and debating powers have been a constant surprise to me—I confess I am astonished at finding myself in the chair. But I have other feelings not less strong than my sense of your kindness. Dignities ever bring with them responsibilities and cares, and this one is no exception. I am very conscious of the difficulties of the position in which your favour has placed me—difficulties peculiarly great under existing circumstances—and I could not, and I would not accept the distinction, were I not quite sure of your kind and constant support and aid. I have every confidence in the future of this Council; and, notwithstanding all that has been said against it out of doors, I can scarcely believe that when the profession delegate twenty-four picked men from the three divisions of the kingdom, to come here to work hand and heart, as I can testify they do work, in order to

grapple successfully with the great and important subjects that are continually brought before them, I can hardly believe that their labours will be resultless. There must be some time between seed-time and harvest. Nature tells us so. But I know that the good effects of our labours are manifest to those who are willing to see them. I know, too, that the ground has been well tilled, the ground has been cleared of weeds, the seed has been sown; I know that the crop is growing, and those who do not wilfully shut their eyes may see it; and I am very sure that before long there will be a rich and abundant harvest.

Mr. CESAR HAWKINS, who had also been put in nomination for the presidential chair, briefly replied, thanking those members who had proposed and supported him, and congratulated the members in the election of so worthy a successor to the chair just vacated by the resignation of Dr. Burrows. Had he (Mr. Hawkins) been elected to so exalted a post he should have accepted the honour with great reluctance, considering that there were many others at the table better qualified to discharge the duties incumbent upon the office than himself. But he would have accepted it upon public grounds, and upon those grounds only. He again congratulated the members upon the excellent choice they had made. The Council then adjourned at half-past six.

SATURDAY, JULY 10.

The Council met this day at one o'clock, and proceeded to elect by ballot the Executive Committee for the ensuing year. The members chosen were Dr. Bennett, Mr. Hawkins, Dr. Acland, Dr. Andrew Wood, Dr. Aquilla Smith, Dr. Sharpey.

The report and balance sheet of the Finance Committee was on the motion of Dr. Sharpey, read and adopted.

Dr. ANDREW WOOD then rose to call attention to the great excess of expenditure over the income of the Council, and suggested as a means of reducing the expenses of the Council, that henceforth the members should only be paid for six days' attendance (thirty guineas) however long the sittings might continue; and that any member absenting himself after the six days should forfeit three guineas each day for such absence.

The foregoing motion and suggestions of Dr. Andrew Wood gave rise to a very long and animated debate, in which Sir Dominic Corrigan, Dr. Alexander Wood, Dr. Smith, Dr. Parkes, Dr. Fleming, Mr. Cooper, and others took part. The general tenour of these speeches was decidedly against any reduction being made in this respect, the majority preferring to give their services without any emolument at all, rather than submit to the indignity. Dr. Risdon Bennett was exceedingly warm in denouncing the plan brought forward; maintaining that as the Council had been primarily constituted by the Privy Council, and the utmost faith in its labours had been reposed by Government, upon principle and upon principle only would he vote against such a motion. He believed not one at the table came there from any mercenary motives; he could safely say there was not a member of the Council who peculiarly gained anything by his attendance. Why, then, continued Dr. Bennett, should they, in the face of what was going on at the present time out of doors to stem the tide of gratuitous services, or services inadequately paid, be the first to submit to this cheese-paring process? It was an indignity that should never have been offered to such a body of men as sat at that Board.

Dr. CHRISTISON was of the same opinion, remarking that if certain members practised their oratory a little less, and which he could not help saying was often intended otherwise than for the Council, much valuable time now wasted would be saved, and with it some of the heavy expenses it was now sought to reduce by other means.

Mr. HARGRAVE remarked that the quantity of gas expended in some of the speeches that were sometimes delivered there was remarkable.

Dr. STOKES was strongly adverse to the proposal of Dr. Wood; but he was equally unprepared to support the proposal hinted at by some members for gratuitous services, although the fees received for attendance was unworthy of consideration to the majority of the members present. It nevertheless acted as a kind of moral compulsion to ensure such attendance. He was in favour of limiting the length of the speeches, the business of the session could thus be got over in half the time, and the reduction of expenses would be obtained in a far more satisfactory and acceptable way than that sought in the motion before the Council.

Dr. SMITH considered that as they came there for the purpose of working for the profession they should be paid for their labours. No other profession would work for double the fees paid them, and yet they were asked to work for nothing. He considered such a motion was degrading, displaying a decided wish to pander to certain classes out of doors.

Dr. QUAIN explained that the reason he seconded the resolution of Dr. Andrew Wood was on the same grounds that a commercial man would, when he found his expenditure exceeded his income, set about reducing the former. The expenses of the Council over its receipts was very considerable, and if by reducing the length to which speeches extended they could confine the business of the session within six days so much the better. Personally he should be very happy, if it were deemed desirable, to give his services gratuitously, and he knew others would cheerfully do the same.

Dr. ANDREW WOOD, in reply to the severe remarks that had been passed, said he felt bound to vindicate the course he had adopted. Next year, he said, the Council would find itself short of something like £575. Why, then, should he be accused of mean or mercenary views, or of pandering to the wishes of a certain portion of the profession, because he adopted the only course open for reducing the large and yearly increasing expenses of the Council? There had also been some very strong animadversions upon the lengthy and inflated speeches the Council were wont to listen to from certain members; while Dr. Christison went so far as to accuse some gentlemen of speaking to those out of doors, for the purpose of displaying their oratorical powers. He considered this a most unjust accusation. He did not know to whom Dr. Christison alluded, but of this he was certain, that every one sitting there was quite as much in earnest as those who had made the accusations. It was all very well to taunt them with making long and inflated speeches, but had not some of those who made these complaints found their own speeches so highly inflated at times that they came suddenly to a collapse like a balloon? He (Dr. Wood) objected that a gag should be placed upon their mouths, or that they should be limited to five minutes' speech, or any of the propositions that had been made to curtail the liberty of speech. Notwithstanding all that had been said, he should press his motion to a division.

Several amendments were then proposed; ultimately an amendment by Dr. Fleming was carried, "referring the subject to the Finance and Executive Committee."

The following report of the Committee on Medical Education was then presented, and in pursuance of a resolution passed at a meeting on June 26, 1868, the Medical Council passed the following resolution:—

"That a Committee be appointed to consider and report how the various subjects of medical education which have been deemed requisite by the Council may be taught with most advantage; in what order they should be studied; and how the examinations on them ought to be arranged."

A committee consisting of the undersigned being appointed, found that the various subjects of medical education deemed requisite by the Council had been fixed by a resolution of Council (June 7, 1867), and were ten in number—viz.: Anatomy, General Anatomy, Physiology, Chemistry, Materia Medica, Practical Pharmacy, Medicine, Surgery, Midwifery, and Forensic Medicine."

The Medical Council had also fixed a term of four years as the period which should be occupied with medical education before the examination for the licence should be undergone.

In accordance with these resolutions, we addressed the following letter to various teachers who, we thought, would give us the best information. We were not able to address it to all teachers, but we endeavoured to obtain answers from all parts of the kingdom, so that every mode of teaching and every large school might have its representative:

Office of the General Council of Medical Education,
32 Soho Square, London, W.

July, 1868.

SIR,—A Committee of the Medical Council has been appointed to inquire "how the various subjects of medical education which have been deemed requisite by the Council may be taught with most advantage; in what order they should be studied; and how the examinations on them ought to be arranged."

By the recommendation of the Medical Council, four years are to be devoted to the study of the ten following subjects, namely:—1, Anatomy; 2, General Anatomy; 3, Physiology;

4, Chemistry; 5, Materia Medica; 6, Practical Pharmacy; 7, Medicine; 8, Surgery; 9, Midwifery; 10, Forensic Medicine. There must, therefore, be a limit to the extent and detail in which the several branches can be taught.

The above inquiry is restricted to the course of study which is necessary to enable students to obtain the requisite knowledge and skill for the efficient practice of their profession, and is not intended to embrace the fuller courses of study intended for the higher qualifications.

Having regard to the nature of inquiry the and circumstances, as above stated, the Committee would feel obliged by your communicating to them in writing the expression of your opinion on the following points:

1. The topics which may most advantageously be included under the subject of _____

2. The period in a four years' course when _____ can be most profitably studied, and the length of time which should be devoted to _____

3. The manner in which _____ can be best taught—by lectures, practical instruction, or otherwise.

The Committee would also feel obliged by any further observations or information which may occur to you as deserving of attention in connection with the subject of their inquiry.

The Committee beg leave to express their hope that the importance of the subject in question will induce you to forgive the trouble thus proposed, and that you will transmit your reply to me at the above address, on or before the 1st of October, 1868.

I am, Sir, your obedient servant,

(Signed)

JAMES SYME,

Chairman of Committee.

Space does not permit of our giving the Report in full; but for the information of our readers we subjoin a brief summary of those recommendations deemed most desirable:

1st. That the ten subjects deemed necessary by the Council be further sub-divided, for the purposes of teaching, as follows:—1, Physics; 2, Chemistry; 3, Medical Chemistry; 4, Anatomy; 5, General Anatomy; 6, Physiology; 7, Pharmacy; 8, Therapeutics; 9, Medicine; 10, Surgery; 11, Pathological Anatomy; 12, Midwifery; 13, Forensic Medicine; 14, Hygiene.

2. That Physics, Chemistry, Medical Chemistry, Anatomy, General Anatomy, Physiology, and Pharmacy (and Botany if included) be studied previously to passing the first professional examination.

3rd. That in the remaining period of the four years, the other subjects shall be studied, viz., Therapeutics, Medicine, Surgery, Pathological Anatomy, Midwifery, Forensic Medicine, and Hygiene; and that the second, or pass examination shall then take place.

4th. That the exact order, number of lectures, and amount and kind of practical instruction be left to the schools, a guide being furnished to them by a definition of the area in each subject over which the examination will extend.

5th. That the schools institute class examinations in all these subjects, and that the certificate of study shall attest that the student has undergone these examinations.

If the Council approve the policy sketched out in this Report, and decide on carrying it into effect, we suggest that a small Committee, consisting of about five members, shall be appointed, and shall receive full powers to enter during the recess into communication with the various Licensing Bodies with respect to the limits of examination; and that this Committee shall present to the Council, at its meeting in 1870, a definite plan showing the extent to which the Licensing Bodies propose to carry their examinations. This Committee should also have the power to enter into the other matters noted in the Report, especially into the possibility of forming conjoint Examining Boards, before which every student shall appear to entitle him to receive a licence to practise. The Council will then be in a position next year to take definite action in the matter.

ANDREW WOOD, *Chairman.*

The following motions by Dr. ANDREW WOOD, seconded by Dr. PARKES, were then put and carried:

"That the Report of the Committee on Education be taken into consideration at the next session of Council, and that in the meantime the Report, with the Appendices, be submitted to the various Licensing Bodies for their consideration and remarks, with a request that their remarks be sent to the Registrar on or before the 1st December, 1869."

"That a committee of five members be appointed to whom the comments of the Licensing Bodies on the Report of the Committee on Education be referred, and shall have power to discuss with the Licensing Bodies the various points raised in the Report, and embody the results in a report to be sent to the Executive Committee at least one month before the next session of Council."

The Report of the Committee upon Preliminary Education was then handed in, for which we hope to find space in our next.

The following amendment by Mr. CÆSAR HAWKINS, seconded by Dr. ACLAND: "That the attention of the several Licensing Corporations be drawn to the recommendation issued by the Medical Council in 1859, and their opinion asked, whether the time has not now arrived when this recommendation should be carried into effect, and to point out any difficulty which may exist in the way"—was put as a substantive motion, and carried *nem. con.*

The remainder of the sitting, which was an unusually prolonged one, was chiefly occupied in passing some formal resolutions; and the Council adjourned until Monday at one o'clock, in anticipation that it would be the last day of this session.

Correspondence.

THE SYSTEMS OF ELECTION TO MEDICAL APPOINTMENTS IN THE DUBLIN HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I think that the profession and the public are indebted to Dr. Mapother for eliciting opinions on a point of such vital importance to both as the principles which have regulated the election of medical officers to the Dublin Hospitals. But he would have rendered his able paper of more practical value had he dealt with the subject in a wider range, and especially had he unfolded a plan for the securing of *superlative* merit. He dwells on nepotism, and the purchase-system, condemning both, but leaves untouched the more powerful agencies that have ever been in operation—personal and political interest. More men of brilliant abilities and high acquirements have been unsuccessful candidates for hospital appointments through want of influence with *ex officio* governors, than through the antagonism of nepotism or the want of money.

I can see no difference, as a matter of principle, between influence when exerted by the candidate's father or uncle, and influence when exerted by the candidate himself, directly or indirectly, through his family and friends; nor does it appear to me a more unworthy act to sell an hospital appointment than to bestow it under the pressure of personal or political interest. To make an election to such an office as that of physician or surgeon to an hospital come up to the ideal of purity, *all* influences should be excluded. If electors are to be more or less controlled or biased in their judgment, they exercise a wiser discretion when they recognise nepotism and countenance the money qualifications, than when they allow personal or political considerations to have weight.

With respect to the purchase system, it has presented itself in two shapes. In one case money has been paid to a medical officer to induce him to create a vacancy; in the other, the appointment is actually bought by payment of a certain sum.

The first cannot be viewed as an instance of purchase; it is a transaction between the intending candidate and the physician or surgeon willing to retire, therefore the payment cannot control the election. If the payer is to succeed, he must either depend on the recognition of his merits by the governors, or bring some of the influences specified to bear in his favour.

The other is a perfect example of buying and selling, and, though connected with an hospital in which payment of money in any shape for its medical appointments is discountenanced, I cannot but think that there is unreasonable censure cast upon the purchase system as carried out in some hospitals. No doubt a man conscious of his fitness for an hospital appointment must feel it a hardship to be unable to succeed because he is too poor to buy it; but the grievance is the loss of the office, therefore the inability to command any of the other determining influences is equally a hardship. Fortunately for the public, the loss is more to the individual than to the office, since it cannot be argued that the power to command money or interest makes a candidate the less fit for the post.

We have an analogy in other professions. There are men practising for a long time at the Bar, and possessed of great forensic acquirements, who have no prospect of gaining any of the rich prizes in their profession from want of political interest; and yet, will anyone assert that the unsuccessful men would make better judges than those who have adorned and now adorn the Bench?

There is one advantage in the pay system as noticed by Sir Dominic Corrigan, who always takes a deep and comprehensive, as well as a common-sense view of such questions—*viz.*, that the man who pays his money will value the appointment all the more; he will view it as an investment to be improved, in the same way as the general practitioner in England who pays for his practice will work the business so as to guard against the deterioration of its selling value. This is, no doubt, a mercenary view of the matter; but be it remembered that an hospital appointment is not looked for as a mere honourable title, like some of those distinctions conferred by Government for distinguished merit, but on the cold, hard, *unsentimental* calculation of the merchant, as to how far it may lead to private practice, and thus to the increase of professional income.

To ignore professional attainments, and to make the hospital an auction, where its appointments are open to the highest bidder, would be a most reprehensible proceeding; but I am confident that such a practice has not prevailed, and never will prevail in any of the Dublin institutions for the sick poor.

The governors and medical staffs of our hospitals are too high-minded, and entertain too keen a sense of duty to be satisfied with the pecuniary test only, and if they are not, self-interest would counteract the evil, since one incompetent physician or surgeon would damage the reputation of the institution, and drive the class of students from its wards. But Dr. Mapother makes the startling statement, that to the systems of election which have obtained, he ascribes "the fact that the Dublin School, although eminently sound and practical, is remarkably barren of discovery or scientific research." It is difficult to understand the drift of this observation. Is it meant that we are the less distinguished because we are more practical than theoretical? less fit to be hospital physicians and surgeons because we treat diseases more on sound well-tested than on visionary principles? The inquiry is not concerning appointments to professorial chairs in medical schools, but to posts specially designed for the *treatment* of patients, and the teaching of *sound treatment* to pupils. I know not of any scientific research which strictly falls in the path of practice, save what may relate to pathology and organic chemistry. These subjects ought certainly to be studied, but if excellence is to be attained, a life-time must be devoted to their pursuit, and the active duties of the pure practitioner laid aside. If there be few traces in medical literature on these subjects by the pen of Irish physicians and surgeons, the explanation is that here there is no encouragement to nor reward for devoted scien-

tific zeal, as is the case in London and the large capitals on the Continent. The man who, in Dublin, gives up his time to such pursuits, and the better to do so disregards practice, may starve, if he have no private resources. Is it not a fact that young men who, during the first few years of their hospital career, have distinguished themselves in histology and organic chemistry, and even in the field of mechanical invention, are compelled to relax these studies to give themselves increased time to develop what will more surely lead to private practice, the only true source of professional income? The barrenness referred to arises from no want of intellectual fecundity in those holding advantageous posts for research. There have been those who, not caring for income, and looking higher than the ephemeral reputation belonging to a successful career in practice, feeling only the fire kindled by love of science, have produced fruits as rich as have come from any other country. The opponents to the systems of election which have prevailed admit that the Dublin hospitals are officered by some men of great powers, but unfairly argue that their merits are intrinsic and independent. No system can create genius, and none retard its progress; but that system cannot be so bad under which first-rate talent has been procured; at least, it cannot in truth be asserted that it has worked to the exclusion of "men of brains."

But the most zealous supporters of the systems of election hitherto adopted cannot maintain that they are so perfect as not to admit of better. In nothing ought we to rest satisfied with positive quality, but seek what embodies the superlative degree. To act on the principle, "let well alone," is, as Dr. Shaw remarks, to obstruct reform and progress. There is, however, a vast difficulty in finding an unexceptionable substitute for the systems of election which have prevailed. If the question related to promotion from a small to a large hospital, the selection of the candidate would be comparatively easy. Some embarrassment might be felt in determining relative merits, but the task would not be more difficult than that devolving on the Commander-in-Chief of the Army, when he is called on to choose the officer best entitled to be elevated. But it is admitted that at least one member of the medical staff of an hospital should be a junior, and the great difficulty consists in the choice of the *untried* man. The method adopted in some London hospitals, and commended by Dr. Mapother—nomination by the medical officers—is practically as full of faults as any other. Medical men, as Professor Haughton remarks, "are neither better nor worse than their neighbours;" they are actuated by the same motives and governed by the same feelings as other mortals; therefore, the method referred to affords no protection against jobbery, nor security for transcendent qualities. It guards against the election of a downright bad man, but does not ensure success to the best.

It has been suggested by a sound thinker, Dr. Henry Kennedy, and the suggestion has obtained the eloquent advocacy of the distinguished Dr. Shaw, that the tenure of the medical or surgical office should be limited to fifteen years. This method would certainly enlarge the field, but not enrich the soil. It would be to stunt the growth of knowledge, to pluck up the plant before it had reached maturity, and borne fruit. A young man who gets an hospital appointment immediately on his becoming qualified to practise, would, if he have fair ability and industry, gain a good knowledge of disease in fifteen years; but this span is far too short on which to build a solid superstructure. Several years are necessarily engaged in learning; nearly as many ought to be absorbed in testing the results of practice, and thus forming the judgment. We must be careful not to check the full development of practical knowledge in the praiseworthy effort to multiply its recipients.

The plan that naturally occurs to the mind as the most efficient in the case of young unproved practitioners is test by examination: not merely requirements to answer *videlicet*, and to written questions, but to display at the bedside in the hospital how far diagnostic powers and other practical qualities are possessed, and in the lecture-room how far instruction can be delivered orally. The candidate, who, if he be successful, must at once undertake to treat patients and teach students, may well be expected to exhibit good qualities in these respects at the starting point; but experience proves that the power to make a good display in the first instance is no evidence of power to subsequently excel. A young man of moderate ability, but with tact, self-confidence, and self-possession, may undergo the testing ordeal in a manner to make a good impression in his favour, and yet be quite incompetent to reach much beyond his first attainment—to turn to full account the opportunities that hereafter fall in his path. All his powers seem exhausted in the trial, and the first two or three years of hospital practice; they then stagnate, and there is no advance. Sterling talent is often talent being drawn out only where there is a field for action, and then it expands under the exciting inducement of opportunity.

I am far from wishing to make a remark calculated to throw a doubt on the general efficiency of competitive examinations, which are a sure barrier to the introduction of ignorance; but they utterly fail to indicate where lie those special qualities which, when fully exercised, produce a high order of professional skill and accomplishments. For this reason I should prefer to appoint a young practitioner who, while a pupil, was under my observation in the hospital, without submitting him to examination, than take one only known to me as having acquitted himself well at an examination. It is satisfactory to find that I am borne out in this view by two excellent authorities, Sir Dominic Corrigan and Dr. Evory Kennedy.

The question is clothed in difficulty. It is, therefore, the more incumbent upon us not to hastily displace existing systems, because, on searching scrutiny they disclose some defects. My object in making the foregoing remarks is threefold: 1st. To show that the systems which have been followed are undeserving the censure heaped upon them; 2nd, That the proposals made as substitutes are practically as faulty, if not more faulty, than any of the present systems; 3, The difficulty of finding a good substitute.

I am, dear Sir, truly yours,

SAMUEL G. WILMOT.

THE POPULATION QUESTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The pages of your valuable periodical have, for some time past, been, to a certain extent, occupied by some very interesting communications on the subjects of population, pauperism, and other allied and equally important topics. Malthusians and followers of John Stuart Mill have been dilating upon the egregious folly of the poorer classes having large families, and have triumphantly put forward the French population statistics, combined with the generally diffused prosperity of that people, in support of their views.

Now, fully agreeing with those who believe that over-population is a cause of poverty, and that, consequently, it is desirable that a restraint on the growth of population should be in operation, I submit that the remedies which have been hitherto suggested are all objectionable; some on the score of practicability, others on that of morality, and some again are legally criminal. I except emigration and colonization, to which objections may be taken on other grounds; let us review the other suggested remedies.

Mr. Mill, in his chapter on the remedies for low wages, dilates at length on the advantages of *contenance*, and certainly the practice of continence by married couples would seem to be a very natural and effectual check to overrapid propagation of the species; but most persons, the "Dialecticians" included, admit that the general adoption of continence by the classes to whom it would be most beneficial, is altogether impracticable; and Mr. Whittle, with whom I am sure many persons agree, denies its efficacy, and affirms that the inevitable result of a number of married couples attempting to live up to Mr. Mill's idea, would be that "the number of births would in no respect diminish."

Again, the French peasant has been held up as an example worthy of imitation; his family seldom includes more than two children; and it results therefrom that his wages are amply sufficient to maintain himself, his wife and his children, in comparative affluence.

But by what means are those very desirable results attained? Is it by the practice of that continence which J. S. Mill so strongly inculcates? Dr. Drysdale, in your issue of the 30th ult., and in reply to the very pertinent question of Dr. Nourse, admits that he is unable to furnish "the details of French slow increase in numbers," and he is equally incompetent to decide "how this is accomplished;" he does not even hint that it results from the practice of that continence recommended by Mr. Mill, whom he so much and so justly admires. Is it, then, by restraining those desires which actuate every man, and are inseparable from his nature, that population in France has been kept at an almost uniform standard; or is it by the indulgence of these *natural* desires in an *unnatural* manner? Let anyone peruse the case of Mrs. R., detailed in the Sydenham Society's edition of Lancereaux's "Treatise on Syphilis," vol. i. p. 105, and ask himself whether that case throws any light on the subject of the limitations of the number of a family, and the means by which such limitation is accomplished in France. Is this one of "the prudent and common-sense practices of the French people," which Dr. Drysdale "believes to be the best plan" for preventing "the miseries of over-population and starvation?"

Another mode of ensuring small families, which is generally supposed to be commonly resorted to by our continental neighbours, is "*preventive copulation*;" moreover, it is notorious that amongst our Transatlantic cousins, "*habitual fœticide*" is quite an "institution," and lastly there remains Marcus's very effectual plan "*infanticide*."

Here, then, are the much vaunted remedies for low wages, and too rapid propagation,—to wit, (1), *Contenance*; (2), *Unnatural connections*; (3), *Preventive copulation*; (4), *Fœticide*; (5), *Prolicide*; (6), *Emigration*.

With regard to the first of these measures, it has been remarked that its general adoption is impracticable; and Mr. Whittle asserts that it would be inefficient. Concerning the second and third remedies, I would ask, is it desirable that the general community of these kingdoms should be initiated in these brutal practices, which, while morally more debasing and disgusting than masturbation, are, moreover, objectionable from a sanitary point of view, as being productive of disease? No, emphatically no! better far that the increase of population should continue, with its inevitable train of evils, than that our hitherto comparatively pure people should become familiar with the disgusting details of French "*common-sense practices*."

Very little need be said concerning *fœticide* and *prolicide*, both of which may be included in the one category, being simply murder,—as Mr. Whittle forcibly and plainly puts it, "infantile murder before or after parturition." I am sure no political economist, medical or otherwise, will in these days venture to recommend such checks to population, however efficient they may have been found by our French and American friends, in attaining those very satisfactory economical results, so much admired.

Lastly, we come to emigration, and this appears at present to be the only remedy which is at the same time efficient and least objectionable. For that many objections may be urged against it cannot be denied, and amongst these that it is only a temporary expedient, it can only modify and delay the effects of rapid multiplication, for wherever people are they will continue to increase and multiply in accordance with the Malthusian law, so that ultimately a time must come when the population will be too dense for the resources of the earth; then will commence the struggle for food, and then will the human race improve to an indefinite extent, through the

operation of Mr. Darwin's celebrated law of "natural selection;" so that, were we permitted to live so long, we might expect to see a race of men totally superior to ourselves, in the possession of supernumerary faculties and instruments of sense, entirely exceeding us in stature, and probably differing from us in shape to a remarkable degree.

PROFESSOR OWEN'S IDEA OF THE SOUL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Professor Owen, in his "General Conclusions on the Anatomy of the Vertebrates" (vol. iii. p. 820), observes: "Thought relates to the 'brain' of man, as does electricity to the nervous 'battery' of the torpedo; both are forms of force, and the results of action of their respective organs;" and, assuming that the theory is "adverse to the notion of an independent, indivisible, immaterial, mental principle, or soul" (p. 821), he asks, "Is the *soul* of the dog other than the personified sum of his psychological manifestations?"

Here, however, another question arises: What is it that constitutes the distinction in the psychological manifestations of these two widely different species? Does any mere modification of the cerebral organism, any "affection of the cerebral fibres" bring the mind of man into approximation with that which is spiritual? What are the laws which govern those complex modes of thinking and feeling which go to constitute our moral and religious sentiments? Where are the "centres of force" by which the mind is impressed and determined under the influence of these sentiments? In what way can our ideas of an outer world aid us in forming conceptions of anything immaterial (p. 821), except as they affect our self-consciousness in relation to that world, is not very apparent; and volitional manifestations, purely religious, can scarcely be affirmed to be "due to the reaction of lines of force from outside centres upon lines of force put into action from inside centres" (p. 823). The comparison supposed points rather to the conclusion that there may be characteristic psychical differences associated with certain phases of psychical resemblance—differences of such a nature as to warrant the inquiry, "Who knoweth the spirit of man that goeth upward, and the spirit of the beast that goeth downward to the earth?" (Ecclesiastes iii. 21.) That there is something analogous in the two cases is indicated by the form of phraseology applied to both; but we are not to confound analogy with identity in our reasonings on this subject. The laws of chemical polarity give determinate crystalline forms to substances which so closely resemble each other that they might be supposed to be identical, if, by chemical analysis, they were not found to be composed of entirely different elements.

As the learned and accomplished Professor avers his belief in a Divine revelation (p. 821), he will doubtless be prepared to accept its *dicta* on this important question, that "There is a spirit in man" (Job xxxii. 8), that it is something separable from that which is corporeal. "Then shall the dust return to the earth as it was; and the spirit shall return unto God who gave it" (Ecclesiastes xii. 7): and that, whatever may be the essential nature of this animating principle, it is instinct with self-consciousness in its disembodied state. Hence we may not unreasonably suppose that it is the *impress* given to the spirit of man by "the sum of his psychological manifestations," in his moral relation to the Divine Being, which gives significance to the term *soul* as the biological embodiment of the immaterial principle within us.

It may not be deemed altogether irrelevant to the subject under discussion to note that the Hebrew terms, *Ruach* (רוּחַ) and *Nephesh* (נֶפֶשׁ), are employed interchangeably by the inspired writers of the Old Testament, and that, in the oldest cognate language (the Arabic), the correlative nouns, *Ruhhon*, anima, afflatus Dei, from *Ruhha*, respiravit; and *Nafson*, anima, corpus, persona, from *Nafisa*, peperit, enixa fuit,—are thus distinguished by Golius: *Hæc (Nafson), anima corporea; illa (Ruhhon), incorporea.*

I am, Sir, yours, &c.,

Macclesfield.

J. BRICHENALL, M.R.C.S.

CHLOROFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I send you a few remarks on the administration of chloroform, hoping you will be kind enough to give them insertion in your journal.

For the following reasons I cannot regard the rule which at present prevails with regard to position (the dorsal-recumbent), during the administration of chloroform, as a favourable one for the patient.

1st.—There is the pressure of the abdominal viscera, thrown on the lungs and heart, which, of course, interferes to a certain extent with the functions of these organs.

2nd.—The position tends to produce a sinking, or falling in of the anterior wall of the chest (especially during the muscular relaxation resulting from chloroform), thus diminishing its antero-posterior diameter, and, therefore, unfavourable to respiration.

3rd.—The position favours gravitation towards, and congestion of blood, in the posterior parts of the lungs, especially if the inhalation of chloroform be prolonged, thereby further damaging respiration.

4th.—The tongue is thrown backwards, another impediment to free respiration.

Now, when I consider in connection with what I have stated above, the fact that chloroform depresses and tends to paralyze the muscles of respiration and the heart, I cannot regard that position as favourable for its administration which interferes with respiration. But if the narcotism were necessarily deep, or prolonged, I should certainly regard the position as highly dangerous. I do not at present deal with the question as to which would be the best position for the patient during inhalation of chloroform, but may, after a time, give you the views I entertain on this matter.

There, is, however, another and all-important topic, with which the propositions I have enunciated have the closest possible connection—I refer to the treatment of the apparently dead from drowning, in a word, to all cases in which the employment of artificial respiration is demanded. I am sure it is scarcely necessary for me to state, side by side with the above propositions, that I cannot approve of the method promulgated by the Royal Humane Society for the restoration of breathing in the apparently dead from drowning. I allude to the method called Dr. Silvester's. In my first proposition, I say that in the dorsal-recumbent position (the position enjoined by Dr. Silvester's method), there is the pressure of the abdominal viscera thrown on the lungs and heart, which of course interferes to a certain extent with the functions of these organs. But it is well known that in those apparently dead from drowning, water swallowed during immersion is generally found in the stomach, which, by pressing upwards the diaphragm, must interfere with respiration. If, then, the position is unfavourable to respiration without water in the stomach, it is needless to urge that it is much more so when water is present in that viscus in unusual quantity. I have not, therefore, been surprised to learn, whilst reading a late number of your journal, that Dr. Trollope, of Hastings, in treating a patient apparently dead from drowning, found Dr. Silvester's method *utterly futile*, until by placing his patient in the prone position, the latter was relieved at intervals of the large quantity of water which he had swallowed whilst immersed.

I will leave the remaining propositions to speak for themselves. Time does not now permit me to say more on this very interesting subject. But allow me briefly to add, that in those severe cases of typhus fever where the decubitus is dorsal, I believe much injury to the patient may be prevented by due attention to his position on the part of the physician.

Believe me, Sir,

Your most obedient servant,

WILLIAM O'DONOVAN, L.A.H.I.

WEIGHT AND PULLEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In inserting my remarks under the above heading you have made a slight misprint—viz., it should be 28, not 23 years ago I had charge of Sir Philip Crampton's case in the Meath Hospital, and as the adaptation of the weight and pulley to the last case I treated with it, is, so far as I know, *novel*, I give you a brief description of it, should you consider it worthy of notice.

Some time ago I was called to see a young girl, æt. fifteen, suffering from scrofulous disease of the hip-joint of some standing. I found, to relieve the pain in the limb, she had flexed the leg upon the thigh, and retained it so long in this position that no ordinary means could avail to relax it, the muscles being so rigidly contracted. Believing the diseased condition of the hip curable I had to turn my attention to the great deformity I have described, which, if not removed, would render her a cripple for life, and after failing to bring down the limb by all ordinary means, I was compelled to use forcible extension, by which I succeeded in straightening the leg, but the difficulty which then arose was to prevent retraction—she could not bear the pain of any appliance in the way of splint, and I was mortified to see her drawing up the leg again, despite all my efforts to the contrary, when, happily the weight and pulley occurred to my mind as a suitable means to accomplish my object, and immediately I made trial of it with a very small weight at first, gradually increased; this she bore well, and I had the gratification of finding it acted in every way to fulfil my expectations. The girl is now well, and has perfect use of her limb.

Faithfully yours,

HENRY J. SMITH.

Literature.

A TREATISE ON SYPHILIS.*

THIS is an elegantly bound and admirably printed volume; and, coming as it does from a gentleman whose long acquaintanceship with syphilis and urinary diseases has been almost hereditary, it at once claims the most thorough study and attention. We have been much pleased by the amount of practical information contained in Mr. Coulson's work. The man of practical acquaintance with the disease he writes about cannot fail, if he be not a very bad writer indeed, to convey much of his personal experience in his works; but it seems to us that Mr. Coulson has been more than usually fortunate in conveying to the mind of the student those points which are the most valuable for him to be acquainted with. Like most of the younger writers upon syphilis, our author at once confesses himself to be an adherent to the school which the illustrious Bassereau initiated in 1852, that is, he believes completely in the duality of the chancre. In this belief, we must say, we entirely concur with Mr. Coulson. Syphilis always arises from some person who has syphilis, not from a person with only soft chancre. This is our own experience, and we are, therefore, able to congratulate both Mr. Coulson and also Mr. Berkeley Hill on coming to the only conclusion which, we believe, is warranted by the facts before the profession, that soft and infecting sores are different poisons.

His first chapters are devoted to the consideration of the soft chancre. A piece of valuable advice is here given to practitioners who come across such ulcers accompanied by phymosis. Mr. Coulson advises us on no account in such a case to have recourse to an operation for phymosis, because, as he points out, the cut surfaces may become inoculated; and an extensive chancre occur, most difficult to heal. Gangrenous chancres are, it appears, frequently seen among prostitutes at the Female Lock Hospital; sometimes producing frightful ravages, and even sometimes causing death. Such being the case, we are informed by Mr. Coulson, that carbo-sulphuric paste, or chloride of zinc paste, are admirable

* A Treatise on Syphilis. By Walter J. Coulson, F.R.C.S., Surgeon to the Lock Hospital, &c. London: Churchill, 1869. Pp. 351.

applications to such soft chancres. Having full confidence in the doctrine, that soft chancre is merely a local disease, he confines his treatment of it to local remedies, such as *aromatic wine* or solution of sulphate of copper, &c, or sulphate of zinc, &c. frequently changing the applications, when one does not succeed. The local treatment found most useful for gangrene he says is the saturated solution of the potassium-tartrate of iron, kept in constant contact with the sore by means of lint, and changed every four hours, whilst opium is used internally in full doses. Cauterization often fails in serpigeneous sores. Mr. Hutchinson, it appears, has informed Mr. Coulson, that for some time past he has treated patients in the London Hospital suffering from phagedenic chancre, by keeping them day and night in a hot hip bath, at a temperature of from 98° to 100° F., and that, in his hospital experience, he had never found this treatment to fail in arresting the phagedena; healthy action being set up in the part in a week or a fortnight.

In the next chapter we are told how the true mitral lesion of syphilis is usually a chancre; how a period of incubation of some three or four weeks elapses before the part inoculated with the syphilitic virus shows itself in the part inoculated. The true syphilitic primary symptoms are almost always single, unlike the soft sore, which is usually multiple, and the hard bubo of the former contracts with the suppurating and virulent bubo belonging to the soft chancre. Then soft chancre may come again and again in the same individual. A hard chancre is only once seen on the same individual, and whilst soft chancre is auto-inoculable, hard chancre is scarcely ever so. Mr. Coulson, however, seems to agree with Boeck and Bidentkap that a positive effect with the matter of infecting chancre on the patient himself is more easily obtained than M. Ricord's experiments would lead us to expect. The experiments, he says, performed at the Lock Hospital, in 1866, by Mr. J. Lane, Mr. Gascoyen, and Mr. Coulson, appeared to establish the fact, that there is no apparent difference, as far as external appearances go, between the sores which result from the re-inoculation of matter from the non-infecting and infecting chancre. In both cases the resulting ulcers were free from hardness; the period of their duration was the same, averaging from three to four weeks, and the scars which ensued were of the same appearance. These facts are similar to the observations of Professor Boeck. Mr. Coulson seems to treat indurated chancres rationally and simply, with water dressing; and says truly that the sore will in most cases heal readily enough under this simple treatment, unless excessively indurated. Phagedena and sloughing do not so frequently complicate hard chancre as soft. He "cannot recommend mercury" for the initial sore, neither excision by the knife, nor destruction by caustic will prevent constitutional infection.

Non-infecting chancre in the female requires much more care and attention than in the male, and active cauterization should be employed early. The tincture of iodine, and solutions of tannin, are recommended. The chloride of zinc paste is recommended for phagedena in women. Hard chancre is far less frequently met with in women than in men, and it seems that in the Lourcine Hospital at Paris there are not more than fifty such chancres observed annually; but, as the contagious character of *mucous patches*, as our author calls them, is now universally recognised, there is not much difficulty in seeing whence the large amount of true syphilis in Paris arises. With regard to bubo, the characters of chancrous bubo are given—(1) as seated in superficial ganglia; (2) terminating in suppuration; (3) that the pus is virulent; (4) acute symptoms. It is affirmed that blisters will sometimes avert a virulent bubo; but as a rule they generally burst. When they do so our author advises bark and acids, oleum morrhue and the opening of fistule. The treatment of indurated bubo is to let it alone.

And now we come to the doctrine of syphilis; and, first of all, it seems that Mr. Coulson thinks that syphilis arose in 1495 or thereabouts as a *new disease*. In this he runs counter to the views of Lancereaux and others; but, after all, the question seems very insoluble. (N.B. We would remark that there are three mis-spellings of words in page 76, which might be corrected in future editions.) In 198 cases of roseola syphilitica, M. Bassereau, our author truly remarks, was able to confront the patients thirty-four times; and in thirty-one of these thirty-four cases he found that the person who communicated the disease was also suffering from constitutional syphilis. M. Ricord, it appears, "enlightened by the labours of his own pupil and the careful observations of several

distinguished professors at the Lyons school, has unreservedly adopted the dualistic doctrine, and, with his usual industry, has brought forward many additional facts. 134 confrontations were made under his inspection, and all demonstrated to him a similarity of accidents in the patients infected and in those who transmitted the infection to them. Seventy-five of these cases are summarily given in his last edition of the Lectures on Chancre."

How little has been done in this direction in this country all who know the state of the question will allow. According to Mr. Coulson, in chapter eight, mercury does not invariably prevent secondary symptoms. Does it ever do so? The natural duration of roseola is stated by our author as five or six weeks. Syphilitic pemphigus is so rare that our author has not seen a case of it. He considers that rupia is probably a tertiary symptom; we think, on the contrary, that rupia is distinctly a secondary affection. Under the head of diagnosis, Mr. Coulson points out how difficult it sometimes is to distinguish scrofulous from syphilitic ulceration of the fauces. In such cases he "abstains from the use of mercury." In an interesting chapter on malignant syphilis he states that Mr. Hutchinson seems to think that perhaps hereditary taint may account sometimes for the appearance of this formidable disease. Sometimes such cases follow also after phagedenic chancres.

Half-drachm doses of iodide of potassium have been advised by the author in several cases of the kind, with signal success. "In the treatment of malignant syphilis, the most important point is to avoid the administration of mercury. Under the influence of this remedy, the ulcers immediately spread, becomes deeper, and manifest a tendency to gangrene." The essential character of syphilitic iritis, our author informs us, is that of adhesive inflammation; and we may expect to see iritis up to the sixth month after infection. On its first attack, it generally affects both eyes, or with short intervals between the attacks. Mr. Hutchinson believes that subsequent attacks of iritis are relapses, and mentions that one in every five cases of iritis occurred in his experience in syphilitic persons. About one in sixteen cases of syphilis are accompanied by iritis. Mr. Coulson asserts, that all surgeons are agreed as to the efficacy of mercury in iritis. Immediately after writing this, we suppose he would perceive that his colleague Mr. Gascoyen asserted in a paper in the Medical and Chirurgical Society, that specific iritis does remarkably well under a treatment by belladonna and hygienic appliances,—just, indeed, as had long ago been ascertained by Williams of Boston, I. Z. Lawrence, and other specialists.

Syphilitic affections of the larynx occur sometimes early, sometimes late. The early ones comprise inflammation of the mucous membrane, mucous tubercles, and superficial ulcerations. These are generally mild. The mucous tubercle does not appear to be frequently seen in the larynx. The superficial ulcerations often occupy the vocal cords and epiglottis, and are seldom troublesome; it is far otherwise with the laryngeal tertiary affections. In some cases the disease attacks the whole internal surface of the epiglottis, the arytenoid cartilages, vocal cords, and lower part of the larynx, giving rise to deep ulcers of the mucous membrane, destruction of cartilages, necrosis of bones, and constriction of the larynx from cicatrices. When the ulcer occupies the upper part of the larynx, or epiglottis, spasm is produced by fluids. The patient is harassed by constant cough, with purulent expectoration, and dies from exhaustion in many cases. Tracheotomy is sometimes indispensable. Iodide of potassium, not mercury, is recommended by the author, and the parts to be touched by solid nitrate of silver according to Dr. M. McKenzie.

When tracheotomy has been performed in like cases, it seems requisite to use the tube for an indefinite time. With regard to the syphilitic affections of the testes, simple orchitis sometimes occurs, but in the commoner form we find the specific lesion, or true gunny tumour. The tumours in the testes vary from the size of a hemp seed up to a cherry, sometimes isolated, sometimes united. There are but few symptoms of inflammatory action in these cases. We can generally merely detect an indolent enlargement of the testes. If not treated the tumours may lessen, and the testes waste away. When both testes are affected, no spermatozooids are secreted. If left to itself, the duration of syphilitic sarcocele seems to be unlimited; but, "if taken early, and properly treated, it is amenable to remedies, and disappears without unfavourable consequences." Mr. Coulson, in his chapter on syphilitic diseases of the bones, mentions the dry caries of the bones of the cranium the remarkable lesion sometimes discovered *post mortem*.

His 17th chapter discusses the question of mercury or no mercury in syphilis; and the author enrols himself among the ranks of mercurialists. He says truly that many ante-mercurialists have been so rash as to assert that mercury causes all the bad tertiary symptoms seen in the disease; and instances Mr. Syme and Dr. Hermann of Vienna as two gentlemen who have, perhaps, spoken too strongly as to the powers possessed by mercury to produce symptoms in the bones analogous to those of syphilis; but Mr. Coulson hardly attempts to meet the later opponents of mercury, who assert that the disease does far better when mercury is not used; and that the iodide of potassium is the only safe specific to use in syphilis. We shrewdly suspect that our author, just as he seems to know little about the natural history of syphilitic iritis, also knows not much more as to the natural history of roseola, or papular syphilides or other secondary lesions when treated by topical remedies. Perhaps some day he may be inclined to wish to know more about the disease without mercury. Mr. Coulson does not use mercury for primary cases; but, for eruptive lesions, he prefers the mercurial ointment; ʒj. rubbed in, in various parts of the body, every night, Zittmann's treatment, also, finds favour with Mr. Coulson. Some chapters on specific epilepsy, on disease of the liver, lungs, &c., close this most interesting and practical work, which we have no hesitation in recommending all practitioners to peruse carefully, as they cannot fail to learn much valuable information from its pages.

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS—JULY 9.

MEDICAL EDUCATION AND REGISTRATION.

Sir JOHN GRAY—I wish to ask the Secretary of State for the Home Department whether the General Council of Medical Education and Registration, appointed under the Act 21 and 22 Vict., c. 90, represented to the Privy Council, with a view to obtaining the co-operation of that body in improving the mode of educating and examining candidates for medical and surgical degrees, that the official reports forwarded to the Council for their information in the years 1865, 1866, 1867, and 1868 by the heads of the military and naval medical departments, complain of the ignorance of a large proportion of the licensed surgeons and physicians who annually present themselves as candidates for medical employment in the army and navy; and that the tabular returns recorded in the minutes of the Medical Council show that, within the period embraced in the reports named, more than 150 licensed surgeons and physicians who were entitled to hold any Poor Law or other civil medical appointment in the empire, were rejected by the military and naval medical boards as persons to whom it would be dangerous to entrust the lives of her Majesty's forces, because of their ignorance of the profession of which they are licensed practitioners; if the Medical Council did not represent to the Privy Council that seventeen various kinds of medical and surgical diplomas, or degrees, were included in the list of those held by the 150 candidates who were rejected for their ignorance of the elements of professional knowledge, and did they represent to the Privy Council the case of any one of the licensing bodies who issued those degrees or diplomas, with a view to put an end to the granting of licences to practise, which the reports and tables recorded in the minutes of the council prove to be delusive as guarantees of practical medical knowledge; and if the answers to the above questions shall be in the negative, to ask is the Government prepared to take means to secure to the general public the same, or similarly effective, guarantees against the licensing of ignorant and incompetent men who are now employed by the military forces of her Majesty?

Mr. BRUCE—With respect to the first part of my hon. friend's question, I have to state that no such representations have been made by the Medical Council either with respect to candidates rejected upon examination, or with respect to the granting of licences to 150 rejected candi-

dates. I have reason, however, to know that the fact has come under their notice, and occupied their serious attention. In answer to the third part of the question, I have to say that I am informed that the Privy Council is at present in communication with the Medical Council with the view of considering whether the Medical Act should not be so amended as to insure a greater degree of efficiency in the medical profession in the army.

Sir J. GRAY reminded the right hon. gentleman that he had not answered the second part of his question.

Mr. BRUCE—No, sir. No such application has been made.

The House then went into committee on the Contagious Diseases Animal Bill.

Obituary.

JAMES YEARSLEY, M.D., L.R.C.P., &c.

WE regret to announce the death of the above gentleman, which took place at his residence in Savile Row, on Friday last. He was well known to the profession through various contributions to the surgery and pathology of diseases of the throat, nose, and ear. He was the originator and proprietor of the MEDICAL CIRCULAR previous to its incorporation with the MEDICAL PRESS. Jointly with two other members of the profession he started the *Medical Directory*, of which Messrs. Churchill and Sons are the well-known publishers. The deceased was sixty-four years of age.

AMPUTATION OF A LION'S TAIL UNDER CHLOROFORM.

The *Madras Times* says—"We mentioned the other day the severe injury sustained by one of the young lions at the park from a mauling of its tail by one of the tigers in the adjoining compartment. At first there was reason to believe that no dangerous results would follow, but on Friday evening it was judged necessary that a portion, if not the whole of the tail should be removed. Mr. Pritchard and Dr. Miller were requested to undertake the operation, which was successfully performed on Saturday morning by Dr. Miller under chloroform, of which five ounces were used, and the tail was removed close up to the stern. At one time during the operation the animal was to all appearance dead, and did not breathe. The chloroform was stopped, and Dr. Miller went into the cage and commenced briskly rubbing, so as to inflate the lungs, a plentiful supply of water being also poured over the animal. After a brief interval he showed signs of life, and the remainder of the operation was completed, and after a little time the cub was sufficiently recovered to walk about the cage. This is, we imagine, the first and only instance of a lion having his tail cut off under the influence of chloroform.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

TO CORRESPONDENTS.—Several communications and reviews of books are unavoidably postponed.

Dr. ROBERTSON, Portsmouth.—Copies were sent to all the addresses given.

NOTES ON VEGETABLE PARASITIC DISEASES OF THE SKIN, by H. S. Purdon, M.D., Physician to the Belfast Hospital for Diseases of the Skin, received. Early proof shall be sent, as requested.

Dr. F. J. DAVYS, Swords.—Owing to the length of the Council's Proceedings, we are unable to find space in our present number for your communication upon "the Recent Debate of the Statistical Society."

The following Original Communications and Letters are in type, and will appear as soon as space permits:—

On the Treatment of Buboes and their Sinuses (Illustrated), by J. Lamprey, M.B., Surgeon 67th Regiment, Portsmouth.

Obstetric Cases, by J. R. Willan, M.D., Haxey, Lincoln.

AN OLD SUBSCRIBER.—Please see reply to "A Subscriber" below. The authorities of Trinity College do not assist us in publishing the information required, and we do not see that the matter would be so generally interesting as to make it worth while to go beg for the information.

A SUBSCRIBER.—The Colleges and Universities whose pass lists are published by us uniformly send us the information, with a request for its insertion. If the University of Dublin think it worth while to do the same, we may, most probably, give them publicity, but we do not consider it our duty to seek out details of information about individual schools.

COMMUNICATIONS, Enclosures, &c., received from Dr. Apjohn, Dublin; Dr. Alex. Marsden, London; Dr. R. A. Gunn, Chicago; Dr. Rumsey, Cheltenham; Dr. Palfrey, London; Mr. Cooper, Brentford; Dr. Dalston, Brough; Dr. P. A. Cotterell, West Bromwich; Dr. Hardman, Bristol; Dr. Bennett, San Francisco; Mr. J. Cornhill, Birmingham; Dr. Hearne, Southampton; Dr. Moore, Dublin; Dr. Cox, Jersey; Dr. Corrie, Leeds; The Registrar General; Dr. Owen, Liverpool; Dr. Cowen, Kidderminster; Dr. Birchenall, Macclesfield; Dr. Caplin; Dr. Gibbons, San Francisco; Dr. Shinkwin, Cork; Dr. Norris Cane, Waterford; Dr. J. Cresswell, Newcastle; Dr. Birch, London; Dr. Brown; Mr. Cresswell, Norwood; Dr. Robertson, Portsmouth; Dr. Craigie, Reigate; Dr. Harrison, Audlem; Dr. Cowburn, Bampton; Dr. Hardman, Bristol; Dr. Clarke, Scarborough; Mr. J. Winter Jones, British Museum; Mr. Gillott; Mr. Costall, Market Overton; Mr. W. Waterspoon; Mr. Tichborne, Dublin; Dr. Purdon, Belfast; Mr. Coster, Hanwell Lunatic Asylum; Dr. Davys, Swords; Mr. Byron Booth, Manchester; Dr. Day, Torquay; Mr. Spurgin, Stratford; Dr. Waring-Curran, Manchester; Mr. J. H. Levy, &c., &c.

VACANCIES.

University College Hospital.—Resident Medical Officer. Applications before the 17th inst. See advertisement.
Margate Infirmary.—Resident Surgeon. Salary £100, with board and residence.
Sunderland General Hospital.—Assistant House-Surgeon. Salary £30, with board and residence.
Royal Surrey County Hospital.—Dispenser. Salary £70 per annum.
Castlebar Union.—Medical Officer. Salary £20, exclusive of fees. See advertisement.
Mullingar Union.—Medical Officer. Salary £90, exclusive of fees. See advertisement.

BOOKS RECEIVED.

A Physician's Problems. By Charles Elam, M.D., M.R.C.P., &c. London: Macmillan and Co.
Menton and San Remo. By Dr. Edwin Lee. Second Edition. London: John Churchill and Sons.
The Reporter's Guide. By T. Allen Reed. London: F. Pitman.

Deaths.

BOLTON.—On the 11th of May, at Souillac, Mauritius, J. Bolton, M.R.C.S.E., for many years Government Medical Officer for the District of Savanne, aged 45.
GARMAN.—On the 5th inst., at Kent House, Bow road, George Bennison Garman, eldest son of H. V. Garman, M.R.C.S.E., in his 14th year.
GODFREY.—On the 4th inst., Nathaniel Godfrey, Surgeon, of Turvey, Bedfordshire, aged 63.
PHILLIPS.—On the 2nd inst., at Exeter, Dr. P. L. Phillips, of Torville, Torquay.
WATSON.—On the 3rd ult., at Hounslow, Geo. Henry Watson, M.R.C.S.E., eldest son of the late Geo. Henry Watson, Esq., of Charterhouse square, London, aged 33. Deeply regretted by his family and friends.
WESTON.—On the 30th ult., William Weston, M.R.C.S.E., of Battle, Sussex, aged 55.

Advertisements.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments Chemicals, and Trades generally.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

MR. C. WALL, Surgeon-Dentist, 139 Stephen's Green West (late of Parliament street) ONLY attends Patients (unable to pay) gratuitously bearing a note from Members of the Medical Faculty.

ROYAL COLLEGE OF SURGEONS. JULY PRELIMINARY EXAMINATIONS.

DR. MURRAY, Ex-examiner in the Queen's University and Royal College of Surgeons, Ireland, prepares Pupils for the Preliminary Examinations in the latter (and the Apothecaries' Hall) at his Chambers, 28 Trinity College, Dublin.

The Points of Advantage which even the most backward Candidate may here secure are sufficiently obvious. Terms ordinary.

N.B.—Logic and a Modern Language are likely to be added to the Course after July.

CASTLEBAR UNION.

CASTLEBAR DISPENSARY DISTRICT.

North Division, comprising the Electoral Divisions of Turlough, Pontoon, Addergoole, Ballynagoragher, Croaghmoyle and Burren.

MEDICAL OFFICER WANTED for the above Division. Notice is hereby given, that the Committee of Management of the above Dispensary District will, at their Meeting, to be held in the Board-room of the Workhouse, on SATURDAY, the 17th July, 1869, at the hour of One o'clock, proceed to the appointment of a properly qualified **MEDICAL OFFICER** for the above Division (in which he will be required to reside), at the Salary of Ninety Pounds a-year exclusive of Registration and Vaccination Fees.

Candidates must possess the qualifications set forth in the Orders of the Poor Law Commissioners.

Application with Testimonials to be addressed to the Secretary, John C. Larminie, Esq., Spencer Park, Castlebar, up to the hour of One o'clock, on the 17th July, 1869, at which hour Candidates must be in attendance.

By Order,
ROBERT J. NIXON,
Clerk of the Union.

Board-room, Workhouse,
Castlebar, 3rd July, 1869.

MULLINGAR UNION.

CASTLETOWNGEOGHEGAN DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.

NOTICE is hereby given that the Committee of Management of the above District will at their Meeting to be held at the Dispensary, Loughnavally, on TUESDAY, 20th July, 1869, at Twelve o'clock noon, proceed to the election of a **MEDICAL OFFICER** for said District, at a Salary of Ninety Pounds per year, exclusive of Vaccination and Registration Fees.

Candidates must possess the qualifications required by the Poor Law Commissioners. The gentleman elected must reside in the District, and enter on the duties on his appointment.

Applications, with copies of Testimonials to be lodged with the Hon. Sec. before Twelve o'clock on said 20th July inst. Candidates requested to be in attendance.

Rockfield, Streamstown.
Dated this 6th day of July, 1869.
JOHN FALLON, Hon. Sec.

COPAHINE MEZE JOZEAU.

PREPARED by CLERET, French Chemist, 151 Rue Montmartre, Paris. In Chronic recent Diseases, a cure is effected in an average of Six Days. Approved by the Paris Physicians' Academy, Paris Hospitals have awarded a Gold Medal to the Author. Depot for England, G. JOZEAU, French Chemist, 49 Haymarket, London, W.

TASTELESS PILLS—COX'S PATENT.—

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each Pill perfectly tasteless, at 1s. 6d. a gross. Postage 2d. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills from 130 different forms which are kept in stock, will be forwarded free on application to COX and CO., Tasteless Pill Manufacturers, Brighton.

SIX MEDALS—London, New York, Dublin, and Paris.

DIABETES.

BONTHON'S DIABETIC BREAD AND BISCUITS

Have been approved by the Profession and by Diabetic Patients; contain no starchy matter, and are highly palatable and agreeable.

Country Orders punctually attended to.
Address, J. BONTHON, 106, Regent-street, London, W.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued from page 4.)

REMITTENT FEVER.

The prevalence of, and mortality by, remittent fever in India appear to be influenced by length of residence in the country, by station, by season, and by the conditions of the different classes of persons borne upon the rolls of a regiment. For my present purpose it will be sufficient to observe that, according to notes in my possession, the occurrence of, and deaths by, this form of disease among soldiers of the 10th Foot during thirteen years the regiment was in India were as follow, namely:—In the first year of its service there the number of cases was 102, of deaths 11; in the second, 26 and 5 respectively; in the third, 14 and none; fourth, 33 and 6; fifth, 11 and 6; sixth, 2 and 1; seventh, 67 and 4; eighth, 12 and 2; ninth, 162 and 4; tenth, 82 and 3; eleventh, 24 and 2; twelfth, 2 and 1; and thirteenth, 13 and 4. The average rate of mortality, which varied much from year to year, was for the whole period to the cases treated 8·90 per cent. among men, 11·76 among officers, 18·87 among women, and 35·29 among children.

From these and other returns we learn, what has frequently been observed with regard to other diseases, that it is not where the affection is most prevalent numerically that liability to death by it is greatest; neither is the class among which attacks are the most frequent that which furnishes the largest proportion of victims. It is well to observe, however, that, under the term "remittent" fever, two distinct forms of disease are included, both de-

pending upon different conditions, distinguished by different characters, and demanding different methods of management. Of these one, in every respect a marsh fever, similar to the paludal fever of the tropics generally, is termed *jungle fever*; the other, described by Johnson and Martin under the name of ardent remittent fever, occurs in the hottest periods of the year, and for the most part in the more inland districts of India.

The malarial form sometimes prevails as an epidemic at certain stations, and it may be in the recollection of some who read these notes, that so severely were the *Buff's* visited by the disease in this form at Kutnal, that the place was in consequence abandoned. Other places also had a bad reputation on the same account, more especially Dinapore, Butanpore, and Lordianah; the latter station built upon the bank of an old river course. Of late years such recurrences do not take place to anything approaching the extent they formerly did; when cases, however, do occur, they generally happen during the rainy and early part of the cold seasons; and the prevalence of intermittents at the same time is one among several indications that both forms depend upon a common cause.

Of late years such outbreaks may be said to have almost entirely ceased, and a modification has even occurred in the characteristics of the affection. At the time of which I write various circumstances, now happily removed, combined with such as have just been mentioned to induce the form of disease then observed. Of such were overcrowding and imperfect ventilation; another was the enforced confinement of the men in their barracks, errors then practised on the plea of protecting them from the influences of the sun. Thus, when, on the subjugation of the Punjab, our troops held occupation of Lahore, both these causes were powerfully in operation, and produced a severe outbreak in the 9th Lancers and 10th Foot. Then also, and for some time subsequent to that date, the practice permitted in some regiments of issuing spirits to soldiers at or shortly after midday, was a further source of the disease. To obtain them the men often rushed from their rooms to the canteen, exposing themselves to the blazing sun, and, in the North-Western Provinces, to the hot winds then

prevailing. Having swallowed their allowance of spirits, they returned to their quarters, where, after dinner, they threw themselves on their cots to sleep away the remainder of the day, and in not a few instances to pass into fever, or the more fatal form of disease, heat-apoplexy. All these conditions have now ceased, however, and one of the most apparent among the results of improved sanitation has been the decrease in this disease among our troops.

In cases of malarious forms of the affection, various complications occur which are calculated to mask the real nature of the attack. Thus, dysentery or hepatitis not unfrequently supervene, the disease then assuming many of the ordinary characters of enteric fever of temperate climates. As, however, medical officers who have been some time in India have to learn that visceral lesions are often direct results of malaria, they have not, as a rule, much difficulty in assigning their relative value to these and other complications which appear.

In the treatment of intermittent fever it is almost needless to observe that large doses of calomel, and the free abstraction of blood, were for many years considered in the light of *sheet anchors*, for so the phrase went. Both had even before 1840 fallen considerably into disrepute, and have gradually been quite abandoned; yet it may, as a professional curiosity, be here recorded at what cost to himself the medical officer who first dared to dispute the merits of calomel in this disease declined to follow what then was the *orthodox* plan. Dr. Mackintosh, in his work on the "Practice of Physic" (vol. i., page 141), writes that Dr. Halliday, of the India Company's Service, was, by order of the Marquis of Hastings, placed in arrest, and for several years deprived of his rank and pay, because he protested against the mercurial system of treating that disease. The fallacy of pushing that remedy, and bleeding to anything like the extent considered necessary towards the end of last century and early part of the present, has long since been acknowledged; yet the episode just related indicates the cost at which improvements in practice may be attended in the persons of their authors.

The following abstract of a case of the disease under notice will best indicate the means usually employed in treatment at the time of its occurrence, namely:—

Cumming, 10th Foot, aged twenty-one, only three months in India, admitted into hospital 22nd September, 1857, suffering from ardent pyrexia and intense heat of the epigastrium; he had been ill three days. There were indications of great congestion of the lower lobe of the left lung; the tongue was brown and dry; he laboured under a sense of general oppression; the pulse was small and labouring. He was freely *soused* with water; calomel and croton oil were administered, and leeches applied to the affected side. On the 26th, he expressed himself as considerably relieved; oppression was manifestly less; the skin had become cooler, although the temperature at the epigastrium continued higher than at any other part of the surface. The state of the bowels continued relaxed. Ordinary diaphoretic mixture was ordered. On the 27th, the appearance and sense of oppression had still further diminished; pulse was small and contracted; the sensation conveyed from the surface was more natural than it had been; the tongue continued somewhat dry. Counter-irritation was now applied to the side, and the other treatment continued. On 30th September was expectorating tenacious mucus of a puriform character; all pyrexia gone. Had now quinine in small doses three times a day. On 4th October, the expectoration had decreased; no pain in the chest. The quinine, in one-grain doses, was continued. On the 10th, he was reported as convalescent; expectoration had ceased; medicine omitted. On the 16th, the sounds in his chest were natural; he felt well in all respects, and was accordingly discharged to duty.

Other illustrative cases might readily be given, but suffice it now to observe that not only is it usual to find the different manifestations of the disease differ at certain stations, but that the characters of the attacks, as witnessed at any locality in one year, are often different from

what they are at another. Thus, at one time the head will be chiefly implicated, at another the chest, and at a third the viscera of the abdomen; the disease consequently requiring so many different methods of management.

In connection with the general subject of periodic fevers I would observe that, in so far as my individual experience of quinine has gone, I have not been led to form the superlatively high opinion of that remedy as an antidote or specific which many other medical officers, and, doubtless, of more extended practice than myself, have expressed. I have already given statistics of intermittent fever, which seem to me to indicate that the power of quinine in checking that form has been overrated, and, in my hands, I have never had reason to be satisfied with the advantages of ensuring a state of *cinchonism* over the milder, and, I think, more rational treatment by diaphoretics, evacnants, and free use of cold water externally. I believe that to give to a person suffering from the urgent symptoms of ardent, remittent, or of jungle fever, a half-drachm or two-scruple doses of quinine, and to repeat it after brief intervals, is merely to mask the symptoms which form part of either disease by those induced by the medicine itself; superadding, it is to be feared, the effects of the preparation to those of the influences upon which the disease originally depended; as we frequently see in persons whose inherent powers have enabled them to recover from both; as, for example, in deafness and loss of memory, to which they were for long periods afterwards subject. I have, in my own person, suffered severely from jungle fever and from intermittent fever; but, in neither disease have I experienced much, if any, benefit from the use of quinine, while the effects of even small doses of the medicine, more especially in the latter, were of so unpleasant a nature that to me a paroxysm of the disease was really the less of two evils.

As a prophylactic of malarial fever, however, I join my belief with those who are advocates of its use. Unfortunately for the reputation of medicine as a science, it is a matter of difficulty to establish the direct connection between a particular remedy and effects ascribed to it; but from observation, under a considerable variety of circumstances, I have been led to consider that a judicious use of medicine wards off, if it does not altogether prevent, the recurrence of fevers of these descriptions.

(To be continued)

A PLEA FOR THE CONTROL OF PROSTITUTION.

By T. C. S.

No. 2.

IN a former number of this Journal we laid before our readers a plain statement of facts with regard to the advantages which would be conferred on society, was there such a control exercised over prostitution in Great Britain and Ireland as is carried out on the Continent. We now come to review Dr. Holland's second article on this important subject. He commences it by saying:—

"Having so far described the means by which prostitution is controlled in Berlin, we are naturally led to inquire into the origin of the system." (P. 440.)

"From 1700 up to 1845, one or other form of control existed until the latter year, when against the so-called legalization of crime, an outcry was raised by those who looked upon life from a pulpit only, and believe that the actions of men could be regulated conformably with their own dogmas and theories, nor cease to complain until the last day of December, when all the brothels were closed, and the occupants, with those who lived by clandestine crime, were sent to their native towns, or conveyed out of the Prussian States." (P. 441.)

"Has prostitution diminished since 1846?" From the statistics culled from a work by Dr. Behrend, and given at p. 441, it appears, that in 1839 there were known to the

police from six to seven hundred prostitutes, "while in 1847, a year after these houses were closed, they increased to about 900;" and in 1850 they amounted to the frightful number of 8,000!!! With facts such as these staring the opposers of the system of control in the face, how is it possible that they could be so dead to all feelings of "truth, humanity, and Christianity" as to wish a system to go on which, instead of putting a stop to this vice, has increased the number of its victims to a fearful extent?

But would there be no other good effect produced on society were the control of prostitution in operation in these kingdoms? Dr. Behrend says, "that after closing the houses in 1845, diseases were increased, became more severe in type, and extended widely into the best families; whilst unnatural crimes became more frequent." We think this is sufficient answer to the question we have asked. The author completes his account of the Berlinian system of control with a just and deserved tribute of praise to Dr. Behrend and Herr von Hinkeldey, the President of Police, whose untiring exertions in, we will fearlessly say, the cause of humanity, deserves the highest praise:—

"And though the names of those who endeavour to relieve a class scarcely sinning oftener than sinned against may never be heard amongst the fashionable loungers of our drawing-rooms, yet such philanthropists can fearlessly appeal to time and eternity for a judgment." (P. 441.)

It would be well for some parties who, when they read the title of these articles, will shrug up their shoulders, and elevate their nicely pencilled eyebrows in surprise at the impudence of any person to bring such a subject before the public, could they look back on the pathway of time and say, We, too, have endeavoured to stretch out the hand of charity to a "forlorn and shipwrecked" fellow-being, who, perhaps by one act of indiscretion, has entailed years of endless misery on herself. By this one act she has been bereft "of all, of every stay." By this one act she has been left in a state of total, unprotected weakness. For this one act the world compels her to live on in sin—in misery. Who knows the remorse this class of women suffer but themselves? Who can tell their agonies as, "pinched with cold, and shrinking from the shower," they seek shelter in some hall-door, and strive to drink to keep down the gnawing conscience—the worm that never dies? Tell us not, "they do not feel the degradation of their situation." Tell us not, "they are insensible to kindness." Tell us not that, even when surrounded by all the luxury with which for a time the seducer endeavours to quiet his victim's conscience, they are happy. They may be justly compared to some bird of the tropics confined in a cage with golden bars, and hung up in a conservatory where he sees the fruit and blossoms of his own clime, but, alas! the captive bird knows full well that his native land is far away; what, then, to the bird is the golden cage when its liberty is gone? what the perfume of those rare and costly flowers when they are placed there but to deceive?

The next city we find is Bruxelles. This city, so justly proud of her "Congrès Général d'Hygiène," does not seem to have pleased our author as much as Berlin; he says that:—

"As regards cleanliness, general regularity, and respect for the officers of the commission, there is room for many improvements. We say this reluctantly, for we brought from Bruxelles many pleasing remembrances." (P. 445.)

We perfectly agree with Dr. Holland, that the medical man should see no difference between the slipshod and silk-dressed harlot, nor that the officers of a sanitary commission should imagine that the most degraded, the vilest, nay, the very lowest of this class of society should not be visited in their houses if necessary. The medical man should bear in mind that often in the hour of sickness and distress the mind looks back with regret upon the errors of past times, and frequently resolves to try and break off old vices; he should recollect, that at this particular period

his counsel and reproof will be listened to with respect, and that in all probability, by strengthening these resolutions, he may confer incalculable benefit upon a fellow-being. But one cannot agree with Dr. Holland that,

"Even in the practice of British hospitals we have seen such distinctions made." (P. 445.)

Having been for some time attached to an hospital in which there was a "Lock ward," we think we are capable of speaking rather confidently on this point, and we cannot call to mind a single instance in which there was the slightest difference made between these women; they were all obliged to undergo the same ordeal before admission; they were all compelled to remain in the common waiting room of the hospital for their turn to be prescribed for, and when in hospital their treatment was in every respect similar.

So much were we impressed with the vast amount of good which might be done to these women by kindness, that, though contrary to the rules of the house, we always admitted their friends (not their companions) to visit them, by which means we were enabled to rescue some parties from becoming more depraved. At the time, the question was brought before the board of the hospital, and we received blame for so doing, yet we can now look back upon that period of our life with peculiar satisfaction.

The next city which the author speaks of is Paris. In this city prostitution is divided into two classes, to either one or the other of which the women can belong. One is termed, "*Les filles isolées*," the other "*Les filles de maison*;" the first have separate dwellings, the second "live in the so called houses of tolerance." On being admitted to the first of these classes, the woman receives a card, the form of which is given at page 447, and on the back of the card rules are printed which she must implicitly obey. We would wish to direct the attention of our readers to a few of these:—

— "*They are forbidden to induce to debauchery during the day; they cannot appear in the streets until a half hour after the time fixed for commencing to light the lamps, nor at any season before 7 o'clock p.m., nor remain after 11 p.m.*"

"*They should wear simple and decent apparel, such as cannot attract attention either by its richness, colour, or extravagant form.*"

"*They are forbidden to stop in the public thoroughfares, form groups, walk in companies, go and come within too short limits, or be followed or accompanied by men.*" (P. 447.)

Furnished with this card she appears at the dispensary, where, if found in good health, she receives another card (if not, she is at once conveyed to hospital), which she is obliged to show each time she comes to the dispensary, and which is marked by the medical man in attendance. If our police had the power of compelling any young woman suspected of clandestine crime thus to register herself, and appear at stated periods, an openly acknowledged prostitute, it would be a powerful protection to the virtue of many and many a young girl. We feel not the slightest doubt but that such a course of procedure would diminish clandestine crime more than might be at first supposed.

As regards the opening of a brothel, the officer (of police) requires a written declaration from the landlord, to the effect that he consents to his house being let for such a purpose; and it must be situated at as great a distance as possible from churches public buildings, or offices, &c." (P. 449.)

The rules are much similar to those in Berlin.

Engaged in the control of prostitution there is a staff consisting of twelve medical men, one of whom has the title of chief commissioner; and there are always three of these officers in the dispensary at the time the women attend; besides these there are a great number of police agents, to see that the parties attend regularly at the dispensary. Either class wishing at any period to give up her course of life, and try to obtain a livelihood by legitimate occupation, on stating to the office that such is her intention, she is kept for some time under the surveillance of the

police, and, if found to be going on satisfactorily, she is then released from control.

Though the internal management of the houses in Paris differs somewhat from Berlin, yet everything appears to be conducted very regularly.

In the third-class houses, drink is permitted to be sold.

"And though at first sight this appeared to us a most unwise permission, we were informed that it was tolerated in order to prevent the incessant egress for liquor that occurred when it was forbidden to make sale of drink on the premises." (P. 450.)

We certainly agree with the reason given for permitting the sale of drink in these houses. If any of our readers ever passed the "Coal Quay," they would have seen, some few years ago, the inmates of what in Paris is looked on as a third-class brothel, drinking in the most shamefully disgusting manner at the counter of a public house not many yards from the beautiful "Athenæum." On passing that house we have witnessed sights which would shock the most hardened immodesty; we have heard language which has made our flesh actually creep; we have seen old and young, male and female, going from that house, in the most obscene and disgusting manner, to the wretched hovels in which they eke out their miserable lives. This house became such a nuisance to the neighbourhood, that the police at last were obliged to take cognizance of it, and to have the license of its owner taken from him.

For the control of prostitution in Copenhagen,—

"The police have formed a series of regulations in many respects so similar to those already described as enforced in Berlin that we will only allude to the leading differences between them." (P. 541.)

The principal one appears to be, that in Berlin all the women reside in one house, and the keeper of the house is responsible for their conduct; whilst in Copenhagen they are permitted to live either separately or together, and no person, save themselves, is responsible for their good behaviour. In the police report of that city it is stated "that neither are there in Denmark brothels in the ordinary sense of the term, and as they are found in other countries." This appears to us in the same light as to Dr. Holland. He says:—

"We can see no difference between four or more women living in Denmark, in what they and the chief of the police call a private lodging, and the same number resident in Berlin, in what they and the State call a brothel." (P. 452.)

Our readers will immediately perceive the "palpable evasion" which is tried to be carried out by this statement.

In speaking of "prostitution as it existed and exists in Spain," our author says:—

"To Spain, then, belongs the merit of having been the first to endeavour to control prostitution, and prevent, by medico-sanitary regulations, the spread of disease." (P. 454.)

We regret we cannot agree with Dr. Holland in giving Spain the credit of being the first country where the "control of prostitution" was enforced, for, on referring to Sir Astley Cooper's Lectures on Surgery, vol. iii., page 26, we perceive him quoting from a curious document published by Astruc, in 1347, where, in speaking of the "Countess of Provence and Queen of the Two Sicilies," Astruc says, "She seems to have exercised a very maternal kind of care over the subjects committed to her charge, for this ordinance establishes a public brothel, and lays down regulations for its conduct and management." The regulations were four in number; the most important of which were, that the women should confine themselves within the house, and, by way of distinction, wear a red epaulette on their left shoulders, and that on every Saturday they should be singly examined by the abbess and a surgeon appointed by the directors.

About the same date we are informed, that "there was a public brothel in Southwark" (the part of London where

Guy's Hospital now stands), "under the care of the Bishop of Winchester, the rules and regulations of which are still extant." But we can go still farther back, for in 1162 a Parliament was assembled in Westminster, and an Act passed for confirming the several ordinances, statutes, and old customs of these places, which rules were in force until the reign of the eighth Henry, who, by sound of trumpet and public proclamation, finally suppressed an establishment which, as far as we are capable of judging, must have been a less disgrace to his reign than most of the acts of his own life.

We think these facts prove that Spain is not to be lauded as much as our author would wish; for further information we beg leave to refer our readers to Sir Astley's Lectures, vol. iii., pages 22 and 30.

Neither in Lisbon or Madeira are there any regulations in force. As regards the "Imperial City," "there exist no statistics on this subject, as the government in every way prevents the actual amount of crime being known; and, as a part of this system, the hospital reports are not published." (P. 453.) Dr. Holland concludes by stating, that, from the reports of the Dublin Metropolitan Police for 1851, it appears there were 297 houses, frequented by 1,170 of these unfortunate women, and that in our native city, in the year 1847, there were 200 prostitutes dispersed through 80 brothels, besides 100 who were indulging in clandestine crime.

We have now laid before our readers, in as concise and delicate a manner as we possibly could, the leading features of this system. It is a subject which has always had our warmest sympathies; but, until we read the articles we are reviewing, we were not aware of half the good such a system would confer on mankind.

"How many unhappy creatures go down to their graves uncared for and unpitied we tremble to think; how many drag on a base and hopeless life, may be guessed at by any one who will penetrate into their filthy dens. A police control would at once ensure the lowest prostitutes what we give to our felons—cleanliness, pure air, and some sort of order and discipline. It would give also at all times an outlet from their wretched life, if they wish to avail themselves of it; and it would afford benevolent individuals incalculable aid in their attempts, now, alas! most feeble and ineffectual, to withdraw these women from the inevitable consequences of moral and physical decay." (P. 458.)

"To wipe all tears from off all faces," says Dr. Johnson, "is a task hard for mortals; but to alleviate misfortunes is often within the most limited power."

CASES IN COUNTRY PRACTICE.

By J. R. WILLAN, M.D., Haxey, Lincolnshire.

THE following cases having come under my care lately, may be interesting to some country confrères:—

Birth without pain.—Mrs. Evans, a healthy young woman, in labour with seventh child. A midwife had been with her from 10 a.m. I was summoned about 10 p.m.; found the membranes ruptured, and the arm protruding. There had been a total absence of pain throughout, though the woman was exhausted. I immediately turned and delivered the woman of a male child (dead), though, she informs me, without pain. The placenta came away, and the woman progressed favourably.

Another case I would wish to mention is that of a Mrs. Bedford, who slipped downstairs, and was soon after flooding severely. When I saw her she was almost in a state of syncope; everything drenched with blood. On vaginal examination, the os firm and not dilated. Ordered ice to abdomen, gave acetate of lead, and plugged the vagina. Premature labour was induced; the child born in the bed, without any pain to the mother. Ordered a generous diet, and the woman soon recovered, though still weak.

PROSTITUTION AND THE CONTAGIOUS DISEASES ACT, 1866.

By CHARLES R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.,
Formerly Honorary Secretary to the Harveian Society, V.D.
Committee, &c.

In a recent article on this subject I ventured to express my opinion that the notion, which now appears to be a very popular one in the medical profession, viz, that the only way of diminishing the extent of venereal contagion in this country was to be found in the extension of an Act passed in 1866 for the Army and Navy to the general population was erroneous. I asserted that it was not the only solution of the difficulty; nay, more, I contended that it was a very inadequate and rough mode of meeting the question, and that, in short, I was on the whole quite opposed to the extension of the provisions of the Contagious Diseases Act to the general public.

The result of my observations has been to call forth several interesting letters from one or two eminent members of the profession, with whom I had formerly the honour of associating in the Harveian Society Committee. As I much respect the arguments of all who differ from me I shall endeavour to reply to them *seriatim* in this place. Thus, one surgeon of immense experience writes:—"I believe the present Act, if extended, would be of immense service in diminishing disease, infinitely more so than the French system, for many reasons. . . . I also think that in this case, as in all others, personal liberty should not be permitted to stand in the way of general welfare, and that we are perfectly justified in preventing persons when diseased, from following a calling for a livelihood, which necessarily involves the spread of that disease."

I readily enough admit the general rule that the greatest happiness of the greatest numbers ought to be the guide to all sound legislation; only I demur to including this infringement of the Habeas Corpus Act among the cases to which this axiom is applicable. No doubt "utility" is the grand end at which we should aim; but then justice is the highest of all utilities, and I am convinced that my most respected correspondent will perceive that it is quite impossible to reconcile with equal social justice the shutting up of a woman in a hospital for months against her will, whilst the man who infected her is allowed to go away, and infect as many other women as he pleases. None know this rent in the measure better than the Parisian medical men; hence, Auzias Turenne's remark that the women there are nothing but "white slaves." Mr. Berkeley Hill, one of the most ardent admirers of the extension of the Contagious Diseases Act of 1866, is, in common with several of his able family, far more enamoured with police interference than I am; and in a letter in a morning paper from Mr. J. S. Mill, that gentleman thus adverts to the topic under consideration:—"I believe many of those who wish for the permanent surveillance of criminals are desirous also of establishing prostitution on a legitimate basis. I think them completely wrong in principle, and mistaken as to the practical benefits which seem to arise from such a plan." Such is the assertion of Mr. Mill as to the practical result of putting prostitution under the surveillance of the police. Having resided much in France, that gentleman is well aware of all the arguments used for and against the French system of surveillance. Of which more anon. In the meantime I desire to notice another private letter from a most distinguished and amiable surgeon, who thus writes me:—"I quite disapprove of putting the girls under the surveillance of the police for purposes of medical examination. Such a practice is most demoralizing; but I would have hospitals where they could readily and quietly get cured when ill. These hospitals should be so arranged that a girl once admitted should be compelled to remain until well. They should not be received as 'sinners,' nor

should the treatment differ from that of usual hospital patients. I see that some time ago at the Lock Hospital, some of the patients broke windows, &c. . . . I should not allow 'visitors,' because the women who keep the houses of reception follow these girls into the hospitals and never give them the chance of getting free. I think that all brothels should be inspected and visited by the police, also registered." This gentleman adds, "You have rightly pointed out the poor girls who make only three shillings a week, or even less. They must, of course, live by occasional prostitution. I had some time ago a quiet and good-looking young married woman under my care, with a little child of three years. She was a needlewoman, but could not maintain herself and child properly without prostitution."

Such are the observations of gentlemen, than whom none in this country are more able to offer a clear and well-grounded opinion as to what should be done for the prevention of venereal diseases, those wide-spread and terrible pests of the human species. And I must now set forth my reasons for opposing, as I do, the extension of the Contagious Diseases Act. In the first place, then, the police system is another of the instances of the subjection of women, and the most offensive of all. The theory of modern society is, of course, that women are to live chiefly by the exercise of one function, namely, the reproductive one. Otherwise, of course, the employments for women would not have been so restricted as to leave that sex scarcely any refuge from destitution save that of becoming wives and mothers. Now, is it not rather hard, that when women cannot get married, and are obliged still to use the generative function as their means of livelihood, almost all others leading, as shown in this last letter, only to 2s. 6d. to 3s. 6d. a week, or to bread, starvation, and tears, the woman should, in addition to this, become thereby a felon, since it is only felons hitherto who could be deprived of their liberty for an indefinite period, whilst the male sex, in addition to its numerous other privileges, should possess this of using these functions with impunity? Still, I know well, that to many this argument is not a telling one. They answer, "All of this is true; but we must try to stamp out venereal disease." Well, now I reply to this, that the experience of foreign States is entirely opposed to the conclusion, that you can thus stamp it out. I have already stated in a former article, that a personal inspection, in 1867, of the Parisian Hospitals convinced me that venereal diseases were even more widely spread in that city, with its police system, than it is in London; that I stated this conviction in the Congrès International, and that far from any *negatur* being made to my assertions, M. Lefort stated to me his conviction that I was quite right. The fact is, the Parisian inspection of prostitutes only leads to a wide-spread clandestine system of prostitution. The same gentleman, M. Léon Lefort, in a recent communication to the Academy of Medicine of Paris, states that the number of tolerated houses has diminished in Paris from 233 in 1840, to 165 in 1867, and that the number of girls attached to them had decreased from 1,976 in 1857, to 1,306 in 1867, whilst this decrease, he adds, has been accompanied by an immense increase of clandestine prostitution, estimated by another authority, M. Lecœur, the chief of the Bureau de Mœurs, at 30,000. Is it to be wondered at that syphilis and other venereal diseases are still so commonly met with in Paris? Indeed, I have no hesitation in avowing my belief, that the French system, which, after all, is identical in most respects with the system so admired by my respected correspondents. (at least, they would, I am convinced, laud in finding the whole of the French details necessary,) tends to ruin the idea of truth and honour among women, and thus to produce the result so well expressed by the above statistics of an immense clandestine sale of their personal attractions to all comers for hire.

In my opinion, and in this I entirely concur with a most learned *compère* writing in the *Westminster Review*, July 1st., 1869, the getting rid

of prostitution and its afflicting contagions is one of the deepest social problems which can engage the attention either of the Legislature or of the medical man. The remedies to which I have before pointed in a former article are early marriages, very small families (so as to improve the condition of the labour market by preventing it from being overstocked by candidates for wages) and lastly the custom of facility of divorce, as advocated by Mr. Conway, at the Dialectical Society, when I had the honour of reading a paper before that most enlightened society of able thinkers.

Mr. Conway on that occasion mentioned that he had in no part of the world witnessed so much domestic happiness or so much freedom from prostitution as in Indiana, U. S., where divorce, it appears, is free to either party, a certain notice (I think six months) being given by one or the other of their intention to separate. On these points my respected correspondents speak as follows:—The last quoted correspondent says,—“Unfortunately, even early marriage will not do away with prostitution. How many married women are there with real or supposed uterine complaints? How many with vaginismus? How many also, who from preference for some one else, or other causes, scarcely let their husbands touch them? Some time ago a gentleman consulted me on other matters, when he mentioned accidentally, that after he had connection with his wife she was seized with uncontrollable sickness and vomiting.

Another told me that he lived apart from his wife because the act made him faint. I think the sooner, he adds, “young people of both sexes marry and emigrate to some rising colony (if not otherwise tied to home) the better it will be for all here.” My reply to the latter desire urged by the author of this letter is, that emigration may and does often benefit those who emigrate; but that owing to the power of doubling our numbers in twenty-five years, emigration never does those who remain in old countries any good, *i.e.*, never raises their wages, or abbreviates one hour of their ceaseless toil. For my part I prefer the early marriages and small families, so prevalent in France, to the attempt to carry off our surplus to the colonies, which never can go nearly fast enough; but it seems that my respected first cited correspondent dislikes this plan. He writes, “Further, I think that early marriages with contrivances to limit increase of population to be generally advocated and adopted, combined with facility of divorce, would be a remedy infinitely worse than the disease, and would be far more mischievous to the moral health of the people, than syphilis is to its physical health.” Now, in this sentence my respected correspondent, after commencing his letter by utilitarianism, appears to me to have slid insensibly into theology and dogmatic assertion. For my part, morality and utility, or the greatest happiness, are synonymous, and I believe that early marriages with small families and facility of divorce would conduce to the greatest happiness. I call these remedies moral, and repudiate. The doctrines which in my opinion have led, and still lead, to poverty and syphilis as immoral.

Finally, my plan for stamping out syphilis in the establishment of hospitals for venereal patients of both sexes on the voluntary principle. I would invite all persons with contagious diseases to enter them, and implore them to remain there until cured. Force I would not attempt. It is not necessary. There are scarcely any prostitutes who could not be persuaded to remain until cured, if threatened with denial of aid at another epoch. In fact, the true genius of Christianity (not its *simulacrum*) would lead us to prevent and cure these terrible contagions, not, as hitherto, to deny admittance to almost all sufferers from them to our hospitals and dispensaries. How absurd, too, to say the prostitute *must* enter hospital when there are no beds provided for them! Try the voluntary system first, and preach early marriage and small families, and in my opinion you will not need the Contagious Diseases Act of 1866.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

FEMORO-POPLITEAL ANEURISM CURED BY COMPRESSION.

Under the care of Mr. PORTER.

THOMAS L., *æt.* forty-two, a housepainter by trade, a man of worn and exsanguine appearance, was admitted into the Meath Hospital, under the care of Mr. Porter, June 13th, 1869, suffering from an aneurism of the lower part of the left femoral artery where it becomes popliteal.

He stated that, with the exception of having had cholera and fever, he had always enjoyed good health, although he had been in the habit of drinking large quantities of whiskey. About two years before his admission, whilst working, he felt a sudden numbness in his left leg, accompanied by a shooting pain from hip to foot. He took off his boot, and saw that his leg was “quite white.” He put his leg into warm water, which gave him relief. From that period until last March, he was from time to time subject to a stinging pain in his knee, which ran down to the foot. On the 17th of March, he went out to row, and, while doing so, missed his stroke, and fell backwards, striking his leg violently against the thwart. Immediately afterwards he perceived a pulsating tumour, somewhat larger than a walnut, above and to the inner side of the left knee. Except an occasional pain in the hip and knee he suffered no further inconvenience until June 6th, when the tumour suddenly became enlarged and painful, and he observed his leg to be swollen.

On his coming into hospital he was found to have an aneurism of the lower part of the femoral artery; it was the size of a large orange, and could be felt pulsating violently on the inner side of the thigh immediately above the knee joint. The circumference of the diseased limb at the situation of the aneurism was fifteen and a half inches, while the measurement of the right thigh at a corresponding point was but twelve and a half inches.

June 14th.—He was ordered a diet of the most nourishing description, meat and eggs being freely allowed, and a moderate quantity of stimulants, to the liberal use of which he had been accustomed. The following mixture was also directed to be given to him, its use being continued through the course of his surgical treatment, with a view to induce coagulability of the blood,—

R Acidi gallici gr. xxxij.
Glycerini fl. dr. j.
Aquæ fl. oz. viij.

Sumat ʒj. ter die.

Digital pressure on the femoral artery was commenced, and kept up on this and the following day, from 11 a.m. till 10 p.m.; but the tumour having only become very slightly, if at all, hardened by the treatment, Mr. Porter, on the morning of the 16th, determined to substitute instrumental pressure. A flannel roller was applied to the extremity from the toes up to the seat of disease, and Read's compressor placed on the femoral artery immediately below Poupart's ligament, Liquoroni's tourniquet being applied a little lower down, at the apex of Scarpa's angle. Directions were given to tighten them alternately, so that the patient might be relieved from the distressing pain caused by the constant pressure upon the artery at one point. The stoppage of the arterial current was only persevered in during the day, the instruments being removed at night, so as to allow of the man obtaining his natural rest.

17th.—Salt's tourniquet tried to-day, but not found to answer, Reid's being the only one which can be borne for any length of time. The tumour is sensibly consolidating, and the pulsation becoming lessened. Each night when the instruments are removed, he gets thirty-five drops of Battley's sedative.

18th.—Pulsation in the tumour has become imperceptible.

19th.—Slight pulsation can again be detected. Does not complain of the pain which is usually indicative of the establishment of the collateral circulation.

July 6th.—From the last date up to this day the same plan of treatment has been persisted in, and the tumour has now become most perfectly consolidated. It pulsed slightly at times, between this and the last date, being, however, for the most part quite free from any beating whatever. The circumference of the limb has diminished an inch since the commencement of the treatment, and this although the man has been gaining flesh during his stay in hospital. He is now perfectly cured, the aneurism—or the remains of it—being readily felt as a hard tumour, which is evidently quite solid, the coagular not yet having had time to be absorbed. During the entire course of this case Mr. Porter endeavoured to stop as completely as possible the current of blood through the sac, as he considers that such is the most essential point in the treatment of aneurism by compression, disagreeing with those authorities who look upon a partial stoppage of the stream as sufficient, and thinking that the more effectually the current is obstructed, the more certain will be the success of the surgeon.

Literature.

THERAPEUTICS.*

THE author of the work before us tells us in his Preface that the work "is designed for students and young practitioners." That to such Dr. Ringer's book will prove most valuable and instructive is a fact that becomes more and more evident the more the work is studied; and, further, it soon becomes equally plain, that the value of the work is by no means confined to those who are young in their knowledge of the art of physic, for we find all that is practically useful in the most recent researches of Buchheim, Stillé, Parkes, and others, set forth in a way that cannot but be most interesting and most useful to those who are quite veterans in the profession.

Early in the book our attention is arrested by a most complete article from the pen of Mr. Clover, on the use of nitrous oxide as an anæsthetic. The remarkable and complete success which has attended the administration of this gas as an anæsthetic in dental surgery is now fully recognised. Mr. Clover explains its action by its preventing oxidation of the nervous centres, for the inhalation of the gas deprives the blood of oxygen in an available form, though it does not prevent the escape of carbonic acid, as evidenced by the analysis of the expired air.

The first part of Dr. Ringer's work treats of alkalies, acids, and certain minerals and their salts, and the way in which these are grouped is well adapted for practical experience. At page 232 we come to the article on alcohol, which, from the pen of one who has devoted so much research to the action of this body on the system, we read with deep interest. The author is one who believes in the value of alcohol in small quantities as an aid to weak digestion, and when given to those who are prostrate with illness, we are recommended to try and give with the alcohol a small amount of food also, the digestion of this being promoted by the alcohol.

Alcohol is stated to be rapidly absorbed, owing to its high diffusive power; and not to pass far down the intestine. That alcohol in the form of port wine does pass into the intestine,

we were able to prove in the case of a woman shown to us many years ago, who had a fistulous opening into the small intestine; port wine taken by the mouth appeared as such after a short interval at the fistula.

With respect to the action of alcohol in diminishing the pre-natural heat of fever-patients, it seems that little is to be hoped from it here, for it is only when alcohol is taken in a poisonous dose, that a fall in the temperature of the body, of 2° or even 3° Fah., is observed; hence, while alcohol is of great use in the treatment of fever, and does in a measure reduce the heat of the body, it is dangerous to give it in such immoderate doses as to lower the temperature in the degree above indicated.

As a remedy to control inflammation and subdue the accompanying fever, aconite is a drug to be very highly esteemed, and its power over inflammation is stated to be little less than marvellous, so that it will at times cut short an incipient inflammation.

We fully believe all that Dr. Ringer says in his most valuable chapter on the use of aconite internally, but we cannot help thinking that though all that is said is true, it is not so entirely new. We have ourselves occasionally employed aconite in erysipelas, since the year 1856, and the very great value of small doses of the tincture of aconite, in cutting short an incipient attack of tonsillitis, has been long ago fully demonstrated by Dr. Prosser James. In the appendix to Dr. James' work on "Sore Throat," are accounts of several cases of inflamed and ulcerated sore throat, cured entirely by aconite, and the body of that work contains full accounts of the drug as a febrifuge, &c. Several years ago the value of small doses of aconite in pericarditis was specially pointed out to us by Mr. Bulley, now consulting surgeon to the Royal Berkshire Hospital. Dr. Fleming's use of it is well known.

The drug treated of next in order to aconite is digitalis, and the pages devoted to this remedy are full of interest and information. It seems that Drs. Fagge and Stephenson, experimenting on the effect of digitalis upon the heart of the frog, came to the conclusion that the action of the digitalis was certainly not to weaken, but to strengthen the heart's contractions, and at last to tetanize the organ.

Two other experimenters, Eulenberg and Ehranhaus, found digitaline to strengthen the contractile force of the heart.

As a remedy in heart disease, Dr. Ringer finds digitalis to act with most advantage when the pulse is quick, irregular, and intermittent, and he lays much stress on using at first a very small dose of the medicine. This precept in our own experience is worth much, and is, to a great extent, the real secret of doing certain good and avoiding unhappy accidents when using digitalis in cases of heart disease.

The article, towards the close of the book, on aloes is not so complete as many of the others; sufficient distinction is not drawn between the different preparations of the aloes, for powdered aloes is an undoubted purgative, yet irritant and pile, causing action is far less in well made ext. aloes aquos., than in the coarser powder form of the drug.

At the close of the book, we find a useful chapter on poultices, and another on enemata, but it seems an omission that in such a work nothing should be said regarding blood letting, and the different ways in which this is accomplished; for we can hardly think that so advanced a therapist as Dr. Ringer should have no experience to give or advice to offer on this matter.

The dietary table appended seems well drawn up and judiciously chosen; and the posological table is very complete and easy of reference.

The index of diseases and their appropriate remedies, too, is arranged in a way calculated to save time and trouble to the busy practitioner. The index of diseases seems more accurate than the final one of medicines. Seeking there for any remarks on "counterirritation" we do not find the word; and on falling back to the word "blisters" we are referred to page 176, but on turning to this page, we find an account of the preparations of zinc.

This apparent anomaly arises from a small typographical error, which is obvious when at page 276 under the head of "cantharides," we find all necessary observations on blisters and counterirritation.

These are but small errors easily corrected, and there remains no doubt that Dr. Ringer has furnished us with a most serviceable handbook on modern therapeutics.

* A Handbook of Therapeutics, by Sydney Ringer, M.D., Professor of Therapeutics in University College, Physician to University College Hospital: London: H. K. Lewis, Gower street. Pp. 485.

TROUSSEAU'S LECTURES.*

If not the most valuable volume issued by the New Sydenham Society, this, now before us, is certainly one of them. It contains a great mass of highly practical matter, and on subjects and diseases most of which are of much consequence to the physician with which to be familiar. The whole, too, is written in the plain strong language for which the lamented author was so remarkable; nor does it seem to us to have lost anything by the translation, which is free and easy, and, we would add, pleasant reading. Amongst the clinical teachers of modern times, none, to our mind, surpassed, if they ever equalled, Trousseau. He must have been naturally endowed, and largely, with what, for want of a better expression, has been called the "medical mind," and this again brought by training to the highest degree of perfection. His natural gifts must have been far above the average, and his memory one of the very strongest; and with an innate love for his profession, and physician to a very large hospital, it can be understood how he reached the highest pinnacle of his art. In many points of view, he must have been singularly like our own Graves; and as Trousseau set up Graves for his model, so we may safely take Trousseau for ours. But it is time to notice more particularly the contents of the volume before us. The volume consists of twenty-one lectures; besides a very valuable introductory lecture, entitled "What is clinical medicine?" The reader will find this an excellent study in itself. It is full of profound observations and reasonings, and a very good sample, if we may so speak of it, of our author's powers. The necessity for constantly seeing disease, and habituating one's eyes to all its variations, is strongly dwelt upon. It is quite true that some will learn from the same number of cases much more than others. But this does not affect the general principle. The first three lectures are occupied by small-pox; the lecturer taking Sydenham for his model, as it were, in describing the disease, and on this model superadding his own experience. And here we may observe that almost all of the old English writers of note are well known and appreciated by our author, who left no stone unturned to make himself the accomplished physician. His description of small-pox, with its varieties and complications, is excellent. One of these is a complication we do not recollect to have seen—we mean orchitis, to which the author draws attention, having met with it himself frequently; but only after he had read an account of its occurrence given by Bereaud, and published in the *Archives Générales*. We may observe, too, that the range of the temperature displayed by the disease is also given. But we must refer our readers to the work itself, where they will find a most graphic account of the disease and its complications. We may notice here that the subject of treatment is very briefly—too briefly we must say—described. The remark applies not only to the lectures on small-pox, but to the entire volume. Indeed, the deficient part of these lectures lies in the treatment. It seems to have been the writer's object more to give a correct account of the disease in all its phases, than to teach any line of treatment. Now, if there be any one of the specific fevers which more than another is benefited by treatment it is small-pox. Over the fever itself we admit our control is very trifling; but when complications arise—and in this affection they are very marked and frequent, often involving life—well-directed treatment is of the greatest value. Besides, at certain stages of the confluent disease, opium in one form or other is invaluable, as laid down long since by Sydenham.

This account of confluent small-pox is followed by two lectures, one on variolous inoculation, and the other on cow-pox. These are each of curious interest, full of valuable material, and show how well versed the author was in all the general literature of the day bearing on the subject. We were not aware till we read it here, that several years before the discovery of Jenner a party (Benjamin Jesty) had inoculated others with cow-pox, for the express purpose of preventing the invasion of small-pox. This comes on authority that cannot be questioned. Yet it does not appear to us to take away in the slightest form the merit of Jenner. Had it not been for Jenner the great discovery might have yet been hidden from the world. For it was he who saw its great value

and worked it out to as full a completion as we believe the subject admits. It was just the same with the vast improvement in the treatment of external aneurism by pressure. This had been accomplished by several before; but it remained for Beltingham to establish it on a basis which cannot now be shaken. One other point in the lecture on cow-pox we cannot pass over. It is the statement that vaccine matter frequently carries with it the syphilitic taint. This is truly a formidable statement, and would appear to be founded on ascertained facts, as given by the author. It has not come under our notice, and we venture to hope that such an occurrence is rare. The signs of syphilis in children are usually so marked that they can scarcely be overlooked. Still, as a tainted child may appear healthy, the utmost caution is requisite. Nor would we place any confidence whatever in the statement that if the pure lymph only—as distinguished from a mixture of lymph and blood—be inoculated this might be done with safety. It would require strong reasons indeed before we could give our adhesion to such an opinion. There remains still another subject, of very great practical importance, to notice. We mean whether a single inoculation is sufficient to protect the system, or whether a greater number renders it still more safe. We confess for ourselves we always thought one vesicle quite enough. Our author, however, states otherwise, and we must allow he gives very strong reasons for what he states. But we must refer to the lecture itself for these reasons. The last lecture connected with this immediate subject is on chicken-pox, which the author believes is a totally distinct disease from small-pox. On this point we must say we have doubts, having seen many cases where the pustules were identical, or seemed so to us, with the form of small-pox known as the discrete. Still the author's opinion is of great weight.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

MR. CROOKE'S PAPER ON THE MEASUREMENT OF THE LUMINOUS INTENSITY OF LIGHT.

THIS subject is susceptible of two divisions—the absolute and relative measurement of light.

A relative photometer is one in which the observer has only to determine the relative illuminating powers of two sources of light. In the ordinary Act of Parliament a standard candle is defined as a sperm candle of six to the pound, burning at the rate of 120 grains per hour. This standard, from which the estimates of the value of illuminating gas are deduced have the terms 12-candle and 14-candle gas. Mr. Crooke points out in his paper the variability of these candles, and has endeavoured to devise a source of light which should be at the same time fairly uniform in its results, would not vary by keeping, and would be capable of accurate imitation at any time and in any part of the world by mere description. The absence of these conditions seems to be one of the greatest objections to the sperm candle. Experiments were made to ascertain whether the electric current could be made available. In practice it was, however, found that many things interfered with the uniformity of the results, and the light being much feebler than it was advisable to work with. The method ultimately decided upon is the following:—alcohol sp. gr. .805, and pure benzole boiling at 81° C. are mixed together in the proportion of 5 volumes of alcohol to 1 of benzole. This burning fluid can be accurately imitated from description at any future time. A glass lamp is taken of two ounces capacity, the aperture in the neck being .25 inch diameter, another aperture at the side allows the liquid fuel to be introduced, and by a well-known laboratory device, the level of the fluid in the lamp can be kept uniform. The wick-holder consists of a platinum tube 1.81 inch long, and .125 inch internal diameter. The bottom of this is closed with a flat plug of platinum, apertures being left in the sides to allow free access of spirit. A small platinum cup .5 inch diameter and .1 inch deep is soldered round the outside of the tube, .5 inch from the top answering the three-fold purpose of keeping the wick holder at a proper height in the lamp, preventing evaporation of the liquid, and keeping out dust. The wick consists of fifty-two pieces of hard drawn platinum wire, each .01 inch in

* Lectures on Clinical Medicine, delivered at the Hôtel Dieu, Paris. By A. Trousseau, late Professor of Clinical Medicine; Physician to the Hôtel Dieu, &c., &c. Volume II. Translated from the edition of 1868; (being the third revised and enlarged edition). By John Rose Coimack, M.D., Edin., F.R.S.E., &c. The New Sydenham Society, London, 1869. Pages 630.

diameter, and 2 inches long, perfectly straight, tightly pushed down into the platinum-holder until only $\cdot 1$ inch projects above the tube. The height of the burning fluid in the lamp must be sufficient to cover the bottom of the wick-holder; it answers best to keep it always at the uniform distance of $1\cdot 75$ inch from the top of the platinum wick. A slight variation of the level, however, has not been found to influence the light to an extent appreciable by our present means of photometry. The lamp with reservoir of spirit thus arranged, with the platinum wires parallel, and their projecting ends level, a light is applied and flame instantly appears, forming a perfectly shaped cone of $1\cdot 25$ inch in height, the point of maximum brilliancy being $\cdot 56$ inch from the top of the wick. The extremity of the flame is perfectly sharp, without any tendency to smoke, without flicker or movement of any kind; it burns when protected from currents of air at a uniform rate of 136 grains per hour. The temperature should be about 60°F ., although moderate variations on either side exert no perceptible influence. Bearing in mind Dr. Frankland's observations on the direct increase in the light of a candle with the atmospheric pressure, accurate observations ought to be taken only at one height of the barometer. To avoid the inconvenience and delay which this would occasion, a table of corrections should be constructed for each $\cdot 1$ inch variation of barometric pressure.

There can be no doubt that this lamp is much more uniform than the sperm candle, and will ultimately replace it in photometric determinations. Mr. Crooke says, "Tested against a candle considerable variations in relative illuminating power have been observed, but on placing two of these lamps in opposition no such variations have been detected." The remainder of the paper is devoted to a description of a photometer, in which the phenomena of polarized light are used for measuring the intensity.

ON THE SOURCE OF FREE HYDROCHLORIC ACID IN GASTRIC JUICE.

PROFESSOR HORSFORD, of America, has endeavoured to solve this important question. The long-disputed position of Prout, that the gastric juice contains free hydrochloric acid, was established by C. Schmidt, who, in an absolute quantitative analysis of the juice, found twice as much hydrochloric acid as was required to neutralize all the bases present. Then comes the question, how could free hydrochloric acid be secreted from the blood, which is an alkaline fluid?

The mucous membrane of the stomach presents, on its inner surface, the mouths of numerous microscopic tubes, which are blind sacs. These tubes as a whole dip into the spongy tissue that underlies the mucous coat, where they are surrounded by the fluid pouring from the net-work of nutritive capillaries, which fluid, as remarked above, contains acid phosphates and chlorides. Now, by pressure and osmosis a portion of this fluid will pass through the walls of the gastric tubes, and the question is, whether the fluid that goes through will contain free acid. The experiments that Professor Horsford performed seemed conclusive. He employed an acid phosphate of lime of specific gravity $1\cdot 117$ of a constitution of $3(\text{Ca OPO}_5) \times 2\text{PO}_5$ with an amount of phosphate of peroxide of iron, present as 1 to 28 of the acid phosphate of lime. The various other solutions employed were the ordinary reagents.

The author used parchment paper to represent the walls of the capillary sacs, also goldbeaters' skin. The parchment paper was made from Swedish filtering paper. In all these experiments the author obtained the same kind of evidence of increased acidity on one side, and increased alkalinity on the other. The same effect took place from a mixture of acid phosphate of soda and chloride of calcium. It follows from the above that if these experiments fairly represent the case, and from the known composition of the blood, its condition in the walls of the stomach, and the structure of the gastric tubules, that free or undecomposed hydrochloric acid must find its way to the bottom of the gastric tubules, and thence into the cavity of the stomach.

Professor Horsford says that he has shown that the acid phosphate pressed from the corpuscles more than neutralizes the alkalinity of the plasma present. In reply it may be said, that the author presents a condition of things in which there is not the kind of physical change required going on, namely, relative augmentation of the corpuscles under pressure, the concomitant of increased supply of blood to the gastric mucous membrane. Its degree must be inferred from the effects on the secretions which he has endeavoured in his paper to point out by conducting an experiment, under what he conceives to

be essentially like conditions, and obtaining the results due to identical conditions. The secretion of hydrochloric acid is, of course, mixed with acid phosphate and alkaline chlorides. These results had been predicted from Graham's researches on dialysis. Phosphate of lime and soda are colloidal, relatively to more crystalloidal hydrochloric acid. Graham found that bisulphate of potassa by dialysis was resolved into two salts or mixtures of greater or lesser acidity than the original bisulphate. So he found that acetate of peroxide of iron was resolved by dialysis into hydrated peroxide of iron and free acetic acid. It is possible and probable that the albuminoid bodies present take part in determining the contrast between colloid and crystalloidal bodies. Graham found that by dialysis he could separate free hydrochloric acid from the gastric juice thrown up in vomiting.

SCOTLAND.

GLASGOW has been very busy speculating what changes would occur should Professor Lister vacate his present appointment by being called to succeed to the Edinburgh chair which Mr. Syme has resigned. There will not be any lack of candidates to succeed Mr. Lister. It is almost certain that Dr. G. H. B. Macleod (brother of Rev. Dr. Norman Macleod), and Dr. George Buchanan, Professor of Anatomy in Anderson's University, and for eight years Surgeon to the Glasgow Infirmary, will come forward, while some think that Dr. Joseph Bell, of Edinburgh, may expect the Lord Advocate's influence to help him, as he is related to him. Dr. Macleod held a high appointment as Civil Surgeon in the Crimean War, and since then he has practised as a surgeon in Glasgow. He is one of the surgeons of the Infirmary, and for about nine years has been Professor of Surgery in Anderson's University. He is a gentleman of great attainments, an excellent lecturer, and a great favourite with the students. His works, "Notes on the Surgery of the Crimean War," and "Outlines of Surgical Diagnosis," are well known, and show how well he has availed himself of his advantages, and how thoroughly he has devoted himself to the study of surgery. Should he be transferred to Edinburgh, the majority of his professional brethren in Glasgow are animated with the hope that Dr. Macleod may be called to succeed Professor Lister.

THE SCOTTISH REGISTRAR-GENERAL'S REPORT.—The returns from the eight principal towns of Scotland show that the deaths last month, 2,686, were by far the greatest number recorded for June since the present system of registration was begun; they are 546 above the average of the last ten years, allowing for increase of population. As throwing light on the causes of disease and on the high mortality which has prevailed during the month, it is worthy of remark that, excepting during the first week of June, not a day passed but the wind blew more or less from the north or east. This unusual prevalence of cold northerly and easterly winds not only reduced the temperature far below its mean, so that over the greater portion of Scotland the hilltops were covered with snow on the 15th, 16th, and 17th of this month, but largely increased the mortality. This increase was not confined to diseases of the respiratory organs, but in almost the same proportion extended to all classes of disease, and especially to those considered as epidemics—viz., fever, scarlatina, measles, and whooping-cough. Zymotic diseases caused 23 per cent. of the mortality, fevers 6·9 per cent., whooping-cough 5·9 per cent. Consumption caused 12 per cent. of the mortality of the month; inflammatory affections of the respiratory organs (not including whooping-cough) 13 per cent. Forty-four per cent. of the deaths were of children under five years of age. The marriages, 1,299, were 73 above the June average. The births registered were

3,393. The mean temperature was 54.4 deg., being 2.2 deg. below the average; the rainfall 2.41, or 0.25 in. less than the average. A great storm occurred at all the stations on the 15th of June, with violent wind and rain from the north-east. It was preceded by a remarkable depression of the barometer during the three preceding days.

WEDNESDAY, JULY 21, 1869.

THE MEDICAL COUNCIL.

THE Medical Council has sealed its own doom. Called together to consider two questions, it has wasted ten days in talk, and relegated both to the limbo of next year. It will surprise few if for it that long-talked of to-morrow never comes. Look for a moment at these questions. First of all, Education has been the watchword of its promises year after year; and what is the result? A miserable *fiasco*. We are presented with a huge volume of answers to a set of questions circulated at random amongst the teachers of ten subjects in the three kingdoms. The Council, if it contain competent teachers, or if it represent the flower of the practical men of the three kingdoms, ought to have been able to do without the mass of opposite opinions from persons of very varying degrees of ability. If previously ignorant on the subject, it ought to have digested it. To print it and refer it to the licensing bodies is an inexcusable waste of the money contributed by the hard-worked practitioners of the land. A crude, undigested mass of material which, so far as we can judge from the amount we have at present read, it is absolutely worthless. Why, some of the answers are little better than advertisements of the individuals who were invited to answer the questions. Professor Syme is to be pitied for having this book thrown at him at the conclusion of all his labours.

Then, as to the second question,—the reform of itself—the Council has proved emphatically how little it represents the profession. The Birmingham Memorial, signed

by more than a fourth of the registered practitioners of the Kingdom, that of the Lothians Association, that of the Garioch Association, were all quietly ignored—referred to a committee, the report of which was not adopted; and no wonder either, for that report was, in the light of these memorials, a positive insult to the profession. If societies like these were ignored, no wonder the representations of individuals were similarly of no effect. Dr. Prosser James asks the Council not to wait for legislation, but forthwith to pass a resolution to the effect that it is desirable for its members to be elected by those who hold the diplomas of the bodies for which they sit.

Such a small instalment of reform as this cannot be got out of the Council. It is therefore fit for nothing but a strong measure at the hands of Parliament. In the letter of Dr. Prosser James it was alleged that some of the members at least sat *illegally*. Is this so? It was hinted in the letter in question that an appeal to the law courts would be effectual, and that the writer would be supported by his professional brethren if he commenced such a contest. We have no doubt of that; but it requires much work, much determination, much money. Whether the Council is worth all this may well be doubted. At any rate, it has proved itself utterly incapable of appreciating the wants of the profession, and the best thing to do with it would perhaps be to abolish it. It has raised expectations it makes no attempt to fulfil, it is inflated with its own self-sufficiency, is deaf to the cry for justice raised by those whose money it has squandered, and year by year is becoming a greater incubus on the profession, while the public neither respects it nor expects any result from it. Would it not be better if it could be dissolved, and a new Council on a broader basis take its place?

Let us hear what our contemporaries say on the subject.

The *Globe* of the 15th, having likened the Council to King Log, goes on to say:—

“Can any enthusiastic advocate of the regeneration which the profession underwent a few years ago point to a single substantial advantage which has resulted from the existence of the Council? The *British Pharmacopœia*? Unquestionably a convenience to prescribers who do not care to carry their knowledge of *Materia Medica* and chemistry so far into detail as to be able to write an intelligible recipe for the particular kind of medicine they may please to use; a wonderful help to men of little knowledge; an immense boon to chemists and counter-practitioners generally, who are in a better position than ever to dispense with, or rather without, physicians' prescriptions; and no mean help to the legion of practitioners whose information in the department of pharmacy is infinitesimally small. Registration under the Medical Act, again, is only an equivocal, and certainly an expensive luxury. Quacks have not been crushed out of existence by the Act, and as a matter of fact it is seldom called into operation except to satisfy some professional spite. The last case that came before the court served to show its weakness. A man can be prosecuted for *calling himself* a physician or surgeon, but not for practising as such, although it may be notorious that he is an arrant impostor. The changes which have been effected in medical education and examination are by no means great, and, such as they are, it is only by a charity which believeth all things that they are attributed to the Council. What has the Council done in the matter of vaccination? Has it devised any scheme by which the public can be assured against the danger of

having its infant life poisoned with the *virus* of the most intolerable diseases? Has the Council represented to Government the deplorable condition in which the law with respect to the registration of 'cause of death' remains? Has it brought under consideration the important fact that not in one case of ten does the certifier know of his own knowledge that his patient is really dead? much less whether the death, especially in the case of young children, was natural in the method as well as cause? Has the Medical Council suggested any improved system of treatment for the poor? Has it done anything to prevent the spread of disease?"

The *Daily News* of the 17th thus summarises the session of the Council:—

"This body has recently held its annual session at the College of Physicians. The debates extended over ten days. Much was expected of it by members of the profession, as it was known that Government had made some communication as to an amendment of the Medical Acts, and that individuals and societies interested in the matter had memorialised the Council to imitate the House of Commons by seeking to place its constitution on a basis satisfactory to all parties. Nothing has, however, been done. The great question of medical education to which Sir John Gray lately called the attention of Parliament has been postponed till next year, and the Council has voted by a small majority that its present constitution is satisfactory, although some of the most influential members refused to join in the discussion, or to take any part in the responsibility of such a resolution. A petition for reform was presented, signed by upwards of 5,000 practitioners, and we are informed that a similar one, more numerous signed still, will be laid before the Ministry. The Council consists of persons chosen by the universities and licensing corporations. It seems that these institutions have allowed their ruling committees to select the representatives. One section of reformers—a very powerful one—demands that each member of the Council should be 'chosen' by those who hold the degrees or diplomas of the bodies. This seems natural, inasmuch as at present a member might be elected by a dozen or a score individuals, not one of whom need of necessity be a medical man. The demand, then, is for an extension of the franchise. This view was strongly urged last year by Dr. Prosser James, when a candidate for the Parliamentary suffrages of the Scotch Universities. He and his followers assert that the member of Council should be elected by as wide a constituency as a member of Parliament, and many hundreds of medical men have supported the plan. Another mode of reform has lately been brought under the notice of Government. It is proposed that some only of the councillors should be elected by the direct votes of medical practitioners. This is called the direct representation of the profession, to distinguish it from the indirect or collegiate. It is not so simple, and there are many obstacles to its being tried. Besides, it would leave the representatives of the universities and corporations, as they now are, the delegates of such infinitesimally small constituencies, that no Liberal Government can look favourably upon it. What is wanted is a compact, strong body, in which the public, as well as the profession, would have confidence. The public would never thoroughly trust the elected representatives of constituencies of twenty or thirty persons. Whether at first or at a later period, an extension of such franchises is sure

to be insisted on. It is, therefore, perhaps to be regretted that the Medical Council has not adopted the resolution which in a well-reasoned letter Dr. Prosser James submitted for its approval."

The *Observer* of the 18th inst. remarks: "This body, whose proceedings last year we fully reported, concluded another annual session last Monday. Two great questions were brought before it. First, that of medical education, on which Sir J. Gray lately commented in the House of Commons; secondly, the composition of the Council itself. Both questions were referred to Committees, and shelved for another year. It is likely, however, they will occupy public attention before then, for we understand that this determination to do nothing has surprised not only active reformers who desired to see something at once done, but even many members of the Legislature.

"More than 5,000 practitioners petitioned the Council, but with no effect, and they will now memorialise Government.

"Last year we stated the constitution of the Council, and the plans proposed to reform it. Our readers will remember that it is composed of delegates from those Universities and corporations which can authorize men to practise. These delegates are chosen not by those already licensed as graduates, or members of such Universities or corporations, but by self-elected committees; so many close boroughs, in fact. Some gentlemen desire to add to the number of councillors a few persons elected by the practitioners of the three kingdoms. This plan is cumbersome, and at variance with all British institutions. The majority of reformers have adopted a scheme first proposed by Dr. Prosser James, and again brought under the notice of the Council this year, but, like the petition already mentioned, shelved by means of a committee.

"This gentleman wishes the representative of every university, college, or other corporation in the Council to be elected by those who hold the medical diplomas of those respective bodies. Besides having been accepted by large numbers of the profession, we are aware that this scheme is heartily endorsed by several eminent statesmen, and shall be much mistaken if it does not form part of any change that may be effected. No Liberal Government can perpetuate the power of a whole series of close boroughs, even on so minute a scale as those which compose the Medical Council. Each member of that body must sit as the representative of a much larger constituency than the twenty or twenty-five persons who look after the details of the corporations. We observe that the balance-sheet of the Council has already got into an unsatisfactory condition; so that the idea of postponing such a reform as has been demanded to satisfy the profession cannot much longer be entertained."

Notes on Current Topics.

Amalgamation of Hospitals.

It has lately been suggested, though on grounds that seem to us very inapplicable, that it might be a good thing for Westminster Hospital to amalgamate with new St. Thomas's, when that magnificent structure shall have been placed at the disposal of the sick poor of the metropolis. There are those among us who entertain the idea that one great [monopoly of teaching would

be a good thing, and who would, therefore, encourage any institution to merge itself in a larger or more showy one. They have faith in the competitive principle for examinations, but no faith in competition among schools of medicine. What has been lost to science by the separation of Guy's and St. Thomas's? Has not the gain infinitely exceeded the loss? and so we may fairly conclude that amalgamation is not to be desired. It would, moreover, be attended with many difficulties. Why should one set of men proclaim the worthlessness of their own instruction, or rather their inability to maintain their school in the efficient condition in which it was bequeathed to them? Of course if it were shown that the staff at any school had become effete, if it were clear they could not impart knowledge to students, that their pupils had little chance of passing their examinations, and less of becoming good practitioners, it would be right and proper for them to give up the attempt, and we should commend their so doing. But no such facts are forthcoming, and no plea for amalgamation exists save the longing for big hospitals and big schools, which is doing so much mischief. Scarpa found an hospital with fifteen beds large enough to occupy him, and his teaching was such as few will gainsay. Let not the mere vanity of those connected with large institutions incite others to hunger after similar appointments. A little work well done is more durable than a mass of routine duty. Small hospitals well administered may yet become the popular model. It will be well for doctors and patients when they do.

Another Personal Attack.

OUR "trumpeting" contemporary cannot exist without personalities, and is too odourate to take warning from the quotation from the *Times* which we submitted last week to its notice. In its last number—which, by the bye, received a dozen "trumpetings" in the advertising columns of the *Times*—it makes a mean attack on another esteemed member of the profession, under the pretence of criticising the appointment of Ophthalmic Surgeon to St. Mary's Hospital. One of the surgeons to that charity, as our readers are aware, is Mr. Haynes Walton, who has also long been surgeon to an ophthalmic hospital. The governors of St. Mary's, upon the sudden vacancy, confide the ophthalmic department to Mr. Haynes Walton, who thereupon resigns his special hospital. For this our contemporary takes every one to task, and, in spite of brilliant examples to the contrary, maintains "it to be absolutely impossible for any man, who practises general surgery conscientiously and well, to keep himself *au courant* with the progress of ophthalmic work during recent years, and that the attempt to do so can end in nothing but failure." There, Mr. Haynes Walton, reflect upon that! Of course every one knows that you have kept yourself so *au courant*. No one doubts you have also practised general surgery conscientiously and well, though the would-be interpreter of professional opinion thus publicly insults you and predicts your failure. For anything that appears in our contemporary's article on the subject, Mr. Walton might be an untried man in any capacity. Disdain your enemy, Mr. Walton. Your name cannot be mentioned without the profession being satisfied that it is all right. People will only laugh and say that the "trumpeting"

paper has been up to its old tricks, and is riled because it could not get the place for some personal friend, who would then have been "trumpeted" to a tune that would have made modest men blush. Mind, however, you keep "*au courant* with the progress of ophthalmic work," lest you should come under the lash of that disappointed rival, and be assailed more virulently than ever. But, even then, "practise general surgery conscientiously and well," though you do it without "trumpeting." See if it may not end in something better than failure. *Nil desperandum*. With colleagues who fear not to trust the department to you, thousands of readers of your writings in practice, many pupils who remember your instruction, the great "trumpeting" purveyor of libel may be again all wrong. But what a curious commentary this outburst is on the virulence with which the same journal has for two or three years treated specialists! It seems it is no use to achieve both a general and a special reputation unless you can make it all right with the "trumpeting" people. A specialist in such a case can be whitewashed. What consistency!

Yellow Fever at Rio.

AN official notification has been received by the various Collectors of Customs to the effect that considerable mortality has taken place at Rio Janeiro from yellow fever, which had attacked the shipping in the Bay. The British Minister at Rio attributes the outbreak of the fever to an unusually prolonged drought and the extreme heat of the weather.

Small-Pox in Sardinia.

A LETTER from Siniscola, in the *Courrier of Sardinia*, states that the small-pox is making terrible ravages in that locality. The epidemic attacks both children and adults, even those who have been vaccinated. The mortality is assuming enormous proportions, and a general feeling of discouragement prevails.

Adulteration of Antiscorbutics.

THE recent legislation adopted for the purpose of putting an end to the disgraceful and inhuman falsification of limejuice, has proved so perfectly efficient, that adulteration of the article is now, after the lapse of two years, almost unknown. The following report of the Inspector of Limejuice for the Clyde District of Ports for the six months ending June 30, has reached the Board of Trade:

"LIMEJUICE INSPECTION.

"SIR,—I beg leave to submit for the information of the Board of Trade the report of the inspection of lime and lemon juice for the Clyde district of ports, for the six months ending the 30th day of June, 1869. The juice inspected was entirely that obtained from lemons, all of it being of excellent quality and generally much above the required standard. None of it was fortified with spirits. The quantity examined was 76 casks, or 7,249 gallons, each of which was subjected to a separate analysis. The average specific gravity of the 76 samples was 1038·6, the average dry residue from one ounce by measure was 40·8 grains, or 28·77 grains in 20 cubic centimetres; and the average proportion of anhydrous citric acid was 31·43 grains per ounce, equal to 34·38 grains of crystallised citric acid. It thus appears that of the dry residue, or solid matter, in the juice, 84·3 per cent. consisted of crys-

tallised citric acid. It must be satisfactory to observe the gradual improvement in the quality of the juice inspected since the Act came into operation. During the first half-year, ending 30th June, 1868, the proportion of juice rejected was nearly 30 per cent. of the whole; for the next six months the proportion was 15 per cent.; and during the last half-year all the juice has been of the required strength. The condition of the juice has also improved very much, the whole quantity inspected during the period of this report being fresh, and in every respect of first-class quality."

This result of well-advised and carefully-framed legislation is a convincing proof that adulteration in other products is perfectly preventible. But it seems it is not accordant with Mr. Bright's "Progressive Liberalism" that we should have commercial honesty; unless it be found convenient to the shopkeeper, and so we must "rest and be thankful" without the security which seems to be so easily attained.

A Public Prosecutor for the Quacks.

WE are happy to announce that there is now some prospect that the measure we have so long and persistently advocated, is likely to assume some definite shape. On reference to the proposed Medical Acts Amendment Bill, it will be seen that a clause was introduced by Dr. Storrar, and unanimously agreed to by the whole Medical Council, "That provision should be made for instituting prosecutions by a public prosecutor, instead of leaving the enforcement of the law to the voluntary action of individuals." If the Government can be induced to take up this matter, and consent to the appointment of a public functionary, as in France and other countries, we shall probably hear no more of those practices which so seriously affect the welfare of the profession and the public at large. As it is, we have almost exhausted the vocabulary in our denunciations of the villainy of quacks, and the subject is now worn threadbare. We have no sooner the satisfaction of seeing one establishment closed, than its occupier crops up in a fresh place, with new trimmings, titles, appointments, and a new name, so that at first we are unable to recognise our old enemy. Occasionally, but, alas, too seldom, they become intimately acquainted with some of Her Majesty's prison warders. But "still they come," and low newspapers teem with their sensuous advertisements, and the post becomes the medium for disseminating their stuff throughout the land. In proof of this, we need but mention, that a highly respectable firm of printers, well known to the profession as the compilers and publishers of "The Visiting List," handed to us some few days since a filthy pamphlet with a letter from the pseudo "Dr. Watson, of South crescent, London, W.C.," requesting an estimate for printing the moderate number of 50,000 copies. Notwithstanding the natural indignation expressed by this firm at being thus insulted, we doubt not that this man, Watson or Hill, or whatever his *aliases*, had little difficulty in getting his dirty production printed elsewhere. At present these quacks carry on their vile but lucrative traffic with impunity; and we hail with delight the prospect of the speedy collapse of a system of plunder and intimidation, for which the Government will receive the sincere thanks of all.

DR. THORNE THORNE has been appointed Assistant Physician to the London Fever Hospital.

MR. SPENCER WATSON, whose name will be familiar to our readers, is candidate for the Assistant Surgeoncy at Westminster Hospital. The election is to take place on the 30th.

A MEDICAL student who has been acting as an assistant to his father, a physician, but who had not yet been registered as a member of the College of Surgeons, was on Friday convicted of having unlawfully practised as a surgeon, and fined £5, with heavy costs.

THE Lords of the Admiralty have, at the recommendation of the Director-General of the Naval Medical Department, resolved that in future the entries of assistant-surgeons into the Royal Navy shall only be decided by competitive examination, in a manner similar to that which exists at Chelsea in connection with the sister service. This is, we understand, only one of the numerous beneficial changes which are to be introduced by Dr. Armstrong.

M. LANDRIN has recently communicated to the Academy of Sciences of Paris a statement to the effect that the poisonous effects of *corralline*—the latest mare's-nest of the *Lancet*—are perfectly imaginary. Our contemporary, it will be remembered, gave the signal some months ago for a general denunciation in the daily press of this dye, and human vanity was threatened with all the penalties of poison if it yielded to the impulse to adorn its legs with red stockings. M. Landrin reports:—(1) *Corralline* is not a poison, even in very large doses; (2) it may be freely used, therefore, in processes which admit of its employment without admixture with other poisonous agents. These conclusions are the result of very numerous and definite experiments made on animals and men under the most varied conditions. In discussing M. Landrin's communication, M. Chevreul remarked that the matter had occupied the attention of the administration of the tapestry works at Les Gobelins, and that, for the purpose of settling it, one of the workmen had not hesitated to cover one of his arms with the pigment. The result of this experiment, like those of M. Landrin, was to prove its absolute harmlessness. Thus it seems that the poison of red stockings may be relegated to the same depository to which the gregarine craze has been consigned. Perhaps the human race will be just as well without either them or chignons; nevertheless, it is unfortunate when a journal hastily gives a scientific stamp to statements which are nothing better than sensationalism.

MEETING OF THE GENERAL MEDICAL COUNCIL.

MONDAY, JULY 12.—TENTH DAY.

THE PRESIDENT, DR. PAGET, in the chair.

AFTER the Minutes of Saturday had been read, the Committee appointed to consider the subject of the Medical Acts Amendment Bill brought up their Report, which was as follows:—

Report of the Committee on Amendment of the Medical Acts.

Committee.

DR. PAGET, <i>Chairman</i> .	DR. APJOHN.
THE PRESIDENT, (Dr. Burrows.)	Sir D. CORRIGAN, Bart.
DR. BENNETT.	DR. PARKES.
MR. HAWKINS.	DR. QUAIN.
DR. ANDREW WOOD.	DR. CHRISTISON.

The Committee on Amendment of the Medical Acts appointed July 1, 1869, in considering the subject remitted to them, have reviewed the various Medical Acts, and also the clauses of the Medical Acts Amendment Bill, agreed upon in former sessions of the Medical Council; and have paid particular attention to the suggestions in the communication from the Lord President of the Council, dated May 14, 1869, and to the several documents referred to them by the Medical Council in the course of its present session, viz.:

Memorial from the Garioch and Northern Medical Association.

Letter from Dr. Prosser James.

Memorial from the Lothians' Medical Association.

Letter from the Parliamentary Committee of the British Medical Association.

Letter from Dr. Bulmer respecting Canadian degrees.

Letter from Dr. Forster respecting registration in the Channel Islands.

Memorial from Dr. Bell Fletcher and numerous other members of the medical profession.

The amendments of the Medical Act, which have been already much discussed and agreed to by the Council in former sessions, consist of clauses which relate—

To the qualification of members of Council.

To regulations concerning the Register.

To the registration of foreign and colonial qualifications.

To additions to the list of qualifications.

To the assumption of titles by unregistered persons, &c.

The Committee recommend that all these clauses, except Clause XI, should be retained in their present form, in any Bill for amendment of the Medical Acts.

With respect to Clause XI, which is as follows, the Committee are of opinion that it should be reconsidered:

"XI. It shall be lawful for the General Council, by special orders, to dispense with such provisions of the Medical Acts, or with such part of any regulations made by authority of the said Acts, as to them shall seem fit, in favour of persons who shall make applications to be registered under the said Acts on foreign or colonial diplomas or degrees: provided such persons shall have resided in the United Kingdom for a period of not less than *twelve months* immediately previous to making application to be registered: provided the holders of these diplomas or degrees have a right to practise medicine or surgery in the countries where they have been granted: and provided the Council shall receive satisfactory evidence that those degrees or diplomas, or licences to practise have been granted after a course of study and examinations such as to secure the possession by persons obtaining them of the requisite knowledge and skill for the practice of their profession."

The Council are aware that the Secretaries of State in successive Governments have, on former occasions, pressed upon the Council the necessity of dispensing with, or greatly relaxing its regulations (by which those who obtain British qualifications are bound) in favour of persons holding foreign or colonial diplomas or degrees. The Council are aware that this condition appeared on former occasions as a *sine quâ non* to the consent of the Government to introduce any Bill for amending the Medical Acts.

The Committee are of opinion that the object aimed at may be attained most simply and safely by a slight modification of sect. 46 of the Medical Act of 1853. This section empowered the Council to dispense with its regulations in favour (*inter alios*) of "persons practising medicine or surgery within the United Kingdom on foreign or colonial diplomas or degrees, before the passing of this Act."

Adopting the form and provisions of the section now cited, the new clause would be as follows:

"XI. It shall be lawful for the General Council, by special orders, to dispense with such provisions of the Medical Acts, or with such parts of any regulations made by the authority of the said Acts as to them shall seem fit, in favour of persons applying to have their names entered on the *Medical Register*, in virtue of foreign or colonial diplomas or degrees." The following is the remainder of this clause as it now stands: "Provided such persons shall have resided in the United Kingdom for a period of not less than *twelve months* immediately previous to making application to be registered: provided the holders of those diplomas or degrees have a right to practise medicine or surgery in the countries where they have been granted: and provided the Council shall receive satisfactory evidence that those degrees or diplomas, or licences to practise, have been granted after a course of study and examinations such as to

secure the possession by persons obtaining them of the requisite knowledge and skill for the practice of their profession."

If this clause should become part of an amended Medical Act, it would then be the duty of the Council to consider how far and in what way its regulations should be relaxed in favour of any person or persons applying to be registered on foreign or colonial diplomas or degrees. The Council would have to consider what is due out of professional comity to graduates of trustworthy and distinguished colonial and foreign Universities, and at the same time not to forget the regard that is due to the rights and privileges of the holders of British diplomas and degrees, which have been obtained after courses of study and examinations supervised and approved by the Council.

The communication from the Lord President of Council invites the consideration of the Medical Council to two points; and on one of these an opinion is expressed that the Medical Act is defective. In this opinion your Committee concur.

They agree with the Lord President in considering that the Act is seriously defective, in that it allows a minimum qualification in surgery to be registered without any qualification in medicine, and similarly a minimum qualification in medicine without any qualification in surgery. The Act indeed not only permits, but requires, the Medical Council to place upon the Register any applicant possessing one such single qualification. The Council has no option or discretion in regard to such applications, but is bound by the Act to comply with them.

The Committee agree with the Lord President in regarding this state of things as open to serious objection, the more so as the number of persons thus practising both medicine and surgery on a single qualification is undoubtedly very large.

It appears, however, from the analysis of titles alluded to in the Lord President's communications, that the number of such persons is decreasing at the rate of about sixty a year, although the total number of persons on the Register is increasing in much larger numbers.

The Committee think that the Lord President should be made acquainted with what the Council have already done in endeavouring to remedy this defect in the Medical Act.

The Council have included both Medicine and Surgery in a list of subjects, which they have recommended to the Licensing Bodies as "subjects without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered."

But the Committee doubt whether the Medical Act would enable the Council to enforce the recommendation on any one of the Licensing Bodies that might refuse to adopt it.

The Medical Corporations and Universities have (chiefly within the last few years) made regulations which, by combining examinations of different bodies, or instituting separate examinations in both medicine and surgery, have done much towards ensuring that persons shall not in future be placed upon the Register without an adequate knowledge of both subjects.

But the Committee are of opinion that the only adequate remedy for this acknowledged defect would be for the Council to accept, under an Amended Medical Act, such powers as would enable them in the future to refuse registration to any person, whatever his legal qualification may be, who has not passed sufficient examinations both in medicine and surgery.

On the other point on which the Lord President's letter invites the consideration of the Medical Council, his Lordship expresses no opinion.

This point, as stated in his lordship's communication, is, "whether, if new legislation is to take place, it would be desirable to change in any respect the constitution of the Council."

In discussing this question, the Committee have fully considered the views and wishes expressed in the memorials and letters which have been received by the Medical Council from members of the Medical Profession.

In reporting on a matter of so much importance as this—whether any, and, if any, what change should be made in the constitution of the Council, the Committee think it their duty not merely to lay before the Council the result of their deliberations, but to indicate also the principles and chief reasons by which they have been guided. There is one principle which is obvious and indisputable, viz., that the constitution of the Council should be such as may best fit it for the discharge of its duties, whatever these may be. In the Medical Act the Council is styled "The General Council of Medical

Education and Registration." The duties imposed on the Council by the Act are four, viz., the supervision of medical education, the registration of qualified medical practitioners, the publication of a national Pharmacopœia, and a certain judicial function, by the exercise of which the name of any registered practitioner "who shall be judged to have been guilty of infamous conduct in a professional respect," may be erased from the Register.

With regard to two of these duties, little need be said. The registration has been made in accordance with the Act, and with an accuracy which has never been questioned. A British Pharmacopœia has been published, which has been universally acknowledged to be one of the best in existence. In this work the task has been accomplished of reconciling the different views and varying practice of the three sister kingdoms. The new British Pharmacopœia is acknowledged in England to be an improvement on the old London Pharmacopœia; in Scotland it is preferred to the Edinburgh Pharmacopœia, and in Ireland to that of Dublin.

In regard, therefore, to those two duties of the Council, there is no reason (but rather the contrary) for proposing any change in its constitution.

With respect to its judicial function thus much must be said—that a Council elected by the suffrages of the profession, as advocated in the memorials, would be entirely out of harmony with the constitution of other courts of justice in the United Kingdom, or, indeed, in any European State whatever. A Council which should be in any considerable part elected by popular suffrages would not be allowed by the Legislature to retain the judicial power which is exercised by the present Council.

With regard to the last and most important of the four duties of the Medical Council—viz., the supervision of medical education, the Council would observe that the powers and means by which this supervision is to be exercised are defined in the Act, sections 18, 20, and 21. These are, in general terms, a power of requiring from the licensing bodies information as to the courses of study and examination to be gone through in order to obtain a qualification entitling a person to be registered, and a power of visiting the examinations; and, lastly, a power of representing to the Privy Council any serious defects in the course of study or examinations of any licensing body, and so depriving the said body of its privilege of granting qualifications until it shall have amended what was faulty or defective.

It is seen, therefore, that all the powers possessed by the Medical Council in respect to education are exercised on or through the medium of the medical corporations and universities, which confer the qualifications entitled to registration. Through supervision and visitation of examinations, and the communication of recommendations, a certain degree of control over the licensing bodies is conferred by the Act on the Medical Council.

Your Committee are of opinion that these bodies, which are in a certain sense and degree governed by the Medical Council, are, for that very reason, entitled to be represented in the Council. This seems no more than is required by justice. Experience has also shown its usefulness in facilitating the adoption by the licensing bodies of the views and recommendations of the Medical Council.

The Committee would observe also that the universities and medical corporations are all, in various ways, peculiarly conversant with education, and with the best methods of testing the acquirements of persons seeking to enter the medical profession, and are thus peculiarly qualified for choosing the fittest persons for discharging those (the most important) functions of the Council which concern medical education and examinations.

The Committee are of opinion that Crown nominees are a requisite element in any body which, like the Council, has not only occasionally to discharge judicial functions, but also to watch over and protect the interests of the profession at large, and secure the welfare of the public.

The Committee are therefore of opinion that the Council as constituted by the Medical Act is well and suitably constituted for performing the functions with which the Council was invested by that Act. The Committee thinks it right to add their opinion that the Council, thus constituted, has, in discharging its duties, met with a degree of success which is large in proportion to the period of its existence, and in relation to the work that had to be done, and the difficulties that had to be overcome. The variety in the views and practice as to medical education and examination which prevailed in

the three divisions of the United Kingdom before the establishment of the Council has, of necessity, added greatly to its labours.

The Committee have very fully discussed certain suggestions contained in the memorials which have been received by the Council. One of these is, that in any Amended Act the control of the Council over the Licensing Bodies should be strengthened and enlarged. If such additional powers were conferred on the Council, the Committee are of opinion that this would be an additional reason for maintaining the representation of these Bodies in the Council as at present.

Another suggestion is for the extension of the powers and functions of the Council over a variety of objects relating rather to professional practice than to education. At present the Council has no powers in such matters. Its powers are defined in the Medical Act, and, as already mentioned, are confined chiefly to medical education. The Council has no power to control the relations either between members of the profession or between them and the Government, nor has it any means of regulating or interfering with in any way the remuneration of the profession, whether for private or public services. It may be a question whether it would be advantageous for the profession that such power should be vested in the Council, whatever the constitution of the Council might be.

But the Committee are (unanimously) of opinion, that if the Legislature should think proper to invest the Council with such extended powers and fresh duties, the members of the profession at large, who would in that case be brought more within the sphere of action of the Council, should have a more direct influence than they have at present in the election of its members. In expressing this opinion, the Committee are fully aware of the many inconveniences that would be incurred, and the many difficulties that would have to be surmounted in any plan for representing the profession in the Council otherwise than as it is now represented, whether by the plan suggested in the memorial presented in the last session from the Committee of Council of the British Medical Association, or by the plan alluded to in some of the documents referred to this Committee, or by any other measure.

The Committee observe that the Lothians' Medical Association complain "that the funds by which the whole machinery of the Medical Act, including the General Council (is carried on), are derived . . . from a tax imposed upon each graduate or licentiate in Medicine and Surgery registered under the Medical Act," and "that such taxation, without commensurate representation of the body of practitioners, is an act of injustice to the great body of registered medical practitioners throughout the country."

The Committee would remark that there can be no difference of opinion as to the principle that liability to taxation entitles to representation in the taxing body. But they would further remark that the fee paid once for all by medical practitioners for entering their names on the Register cannot, in the ordinary sense of the words, be called a tax; and that the Council possesses no power whatever of taxing the registered practitioners.

In the numerous signed memorial from Dr. Bell Fletcher and other members of the medical profession it is suggested that "in any future Act of Parliament provision be made for instituting prosecutions under it by a public prosecutor or other public functionary, on behalf of the General Medical Council, instead of leaving the voluntary enforcement of the law to individuals." The Committee are of opinion that this is a suggestion to which the attention of the Government should be drawn.

The Committee recommend that the letter of Dr. Forster respecting registration in the Channel Islands be remitted to the Executive Committee, with instructions to institute further inquiries on the subject, and, if they think proper, make a suitable representation to the Secretary of State for the Home Department, or other Government authority.

G. E. PAGET, *Chairman*.

Dr. ALEXANDER WOOD moved, and Mr. COOPER seconded—
"That the Report of the Medical Acts Amendment Committee be received and entered on the Minutes." Agreed to.

The Council then entered into a long and critical discussion upon the various points of importance in the proposed Bill, which was brought up as an appendix to the Report. The following was the first motion, which was moved by Dr. BENNETT, and seconded by Dr. CHRISTISON—

"That Clause XI. in the proposed Medical Amendment Act shall stand as follows :—

"It shall be lawful for the General Council, by special orders, to dispense with such provisions of the Medical Acts, or with such parts of any regulations made by the authority of the said Acts, as to them shall seem fit, in favour of persons applying to have their names entered on the *Medical Register* in virtue of foreign or colonial diplomas or degrees."

To this Sir DOMINIC CORRIGAN moved the following amendment :—

"That it appears desirable, before any further attempt is made to introduce amendments of the Medical Acts, that a Royal Commission of Inquiry should issue, to take evidence from such members of the Medical Council, and such other persons as the Commission may see fit to examine, with the view of furnishing a report to serve as the basis for legislation."

In moving the foregoing amendment, Sir Dominic Corrigan said he strongly deprecated the course proposed by the Committee, to send the Bill as it then stood to the Lord President of the Privy Council, as though it came with the sanction and recommendation of the Medical Council, which until then had no opportunity of studying its provisions. He thought it would be far better that the Council should have time to consider the matter, and that it should not be asked to give its decision upon a Report which had but just been presented. It would also be more courteous to the profession at large that its members should be allowed to see and have a voice in a measure peculiarly their own, before the Medical Council gave its decision. He said there was no disguising the fact that the Council were at loggerheads with the profession, and the present was an opportunity that should not be lost of reconciling those conflicting opinions out of doors which had hitherto rendered the proceedings of the Medical Council so unpopular. After the proposed Royal Commission had gone through such evidence as it was able to collect, the whole question of representation and registration had been thoroughly sifted, and the opinions of the licensing bodies and the profession obtained, the Council would then be in a position to send in to Her Majesty's Government a well digested and efficient scheme, drawn up by commissioners appointed by the Council and sanctioned by the Privy Board, upon which to base future legislation. He had heard it objected to, that Royal Commissions were very slow in their operations. He, however, was of quite the opposite opinion; from personal experience he could testify that they did their work well, and that when delays did occur it was generally through committees having, in many instances, to be brought from long distances. These he knew often caused the most vexatious delays. The Council would remember that, in the letter of Mr. Simon (see this Journal, July 7th), it was said that the Government required a measure of a more comprehensive sort as the basis of any future Amended Bill. As far as he (Sir Dominic) had had the chance of studying the proposed Bill, it was far from a comprehensive measure. The Council well knew his opinions also upon the reception of foreign degrees. He had stated before, and would repeat, that diplomas were obtained throughout the whole of Germany, from Denmark downwards, with the greatest facility, and that the Medical Council was asked to recognize the holders of such diplomas, although it had no guarantee by what means they had been obtained, or that any examination had been held previous to granting such diplomas. This would be another subject the Royal Commission would be able finally to dispose of. It was all very well to hold out the right hand of fellowship to the profession of other countries, but then it should be reciprocal, which it unfortunately was not; for in France, if any Englishman dared to practise without having first passed one of the recognized colleges of the country, he was hauled up before the Correctional Tribunal and heavily fined. With reference to the qualifications required before a man should be allowed to practise, he would refer the Council to Clause XX. of the Medical Act, which ran thus—

"In case it appear to the General Council that the course of study and examination to be gone through, in order to obtain any such qualification from any such College or body, are not such as to secure the possession, by persons obtaining such qualifications, of the requisite knowledge and skill for the efficient practice of their profession, it shall be lawful for such General Council to represent the same to Her Majesty's most honourable Privy Council."

If the Report were passed, he looked forward to its results

with the most gloomy forebodings; and he did not consider he should be doing his duty to the body he represented, or to the profession at large, if he did not state thus publicly his objections to such a resolution. The appointment of a Royal Commission was not a hastily-conceived idea, but the result of long and serious study. The opinion had been formed many years since, and all that had been done and said only confirmed his first impressions. Before sitting down, he (Sir Dominic) begged to offer the Council one or two suggestions: the first was, let the Licensing Bodies alone, and leave them to adopt such measures as had been proved to work well; the second was, to have State Examiners, and let the examinations be conducted by a body appointed for the purpose in London, Dublin, and Edinburgh. These Boards should be made responsible for the efficiency of those students whom they should pass. Let them determine the competency of men in whose hands the lives of so many thousands of the poor were placed. He mentioned the poor more particularly, because the rich were able, and well knew how to take care of themselves, and to call in the best advice when needed; but with the poor it was not so. As to the time at which these State Examinations should take place, he was of opinion that they should be after the Preliminary Examinations by the Licensing Boards, as such examination would be a guarantee to the State Examiners that a certain course of study had been already gone through before a competent Board. He then formally moved the amendment of which he had given notice.

Dr. AQUILLA SMITH, as seconder of the amendment, reminded the Council that in 1866 a similar resolution had been proposed, which he then, as now, seconded; and with the additional light of experience, he had not, and could not, alter his views. He was more than ever impressed that, even if the appointment of a Royal Commission was not now agreed to, it must eventually come to it. He admitted that much good had been done by the Council in exposing those Licensing Bodies in Scotland, whose examinations and diplomas were not formerly to be depended upon. On the other hand, much improvement had taken place with other Bodies, without the aid of the Council. He did not believe in the statement that was being continually made, that the Council could do nothing for want of funds. If money were wanted, he need only remark that in 1860 the large surplus of £25,000 was invested in the Funds to the credit of the three Branch Councils; and that, in the Parliamentary returns of the present year, they had the same amount to their credit. The remarks of Dr. Andrew Wood, on the poverty of the profession, were therefore entirely erroneous. The appointment of a Royal Commission would also put an end to the misrepresentations that were being continually made, by different associations, upon the pretext of improving the profession. This was most strikingly shown in Ireland by the ludicrous recommendations and suggestions of the British Medical Association some time since, which showed its utter ignorance of the state of the profession in that country. He cordially endorsed all that had fallen from Sir Dominic Corrigan.

Dr. ANDREW WOOD said that, although he could not agree with some of the remarks of Sir Dominic Corrigan, he nevertheless considered he was entitled to the thanks of the Council for the very temperate way he had brought the matter forward. It had been remarked that the Council were very tardy in its proceedings; but if they calmly reviewed the course taken since its establishment, he thought it must be admitted that much good had resulted from its labours. Large measures like that before the Council required time,—the Medical Act of 1853 took twenty-four years to mature; and this was one cause why he objected to the resolution proposed by Sir Dominic Corrigan, because it would take them back twenty-four years, and be a virtual admission that the Medical Act had been a failure; whereas this could only be said in part. Upon the question of Foreign Degrees, he would only remark that their admission was first proposed by the Privy Council, to which Sir Dominic now desired to entrust the appointment of a Royal Commission of Enquiry. The visitations of Examinations, upon which Sir Dominic had endeavoured to throw cold water, had been of great service to the Council. Such visitations had never failed in their operation, they were a guarantee to the Council that the examinations had been properly conducted, and wherever any abuse existed they had been prompt in applying the remedy. For the appointment of a Royal Commission he was not at present prepared, although he contended that the Council and the profession at large should have the opportunity of studying

the provisions of the proposed Amended Act before it passed into the hands of the Privy Council.

After a few remarks from Dr. ALEXANDER WOOD,

The amendment was put from the chair, and negatived by 13 to 4. The original motion by Dr. Bennett was then put, and carried by the same majority.

The following motion by Dr. CHRISTISON, seconded by Dr. BENNETT, "That in the opinion of this Council it is desirable that power be given to the Medical Council to refuse registration to any one who has not been sufficiently examined both in medicine and surgery," was then put, to which an amendment was proposed but negatived, and the motion agreed to.

Dr. BENNETT then moved, and Dr. ARJOHN seconded, "That the Council are of opinion, that if the Legislature should think proper to invest the Council with extensive powers and fresh duties, by which the profession at large would be brought more under the direct influence of the Council, then in that case the profession at large should have more direct influence in the appointment of members of Council."

Dr. ALEXANDER WOOD said, after the remarks that had been made he should decline to express an opinion upon a measure of the kind proposed, but would be prepared to state his opinions when the proper time should arrive.

Sir DOMINIC CORRIGAN said, the statement of Dr. Bennett, "that the profession was already sufficiently represented upon the Council," was extraordinary when taken in connection with the motion he proposed—which said, *if we get, &c.*, they might as well say, "If the sky were to fall, they would do such and such things." He would, however, do as Dr. Alexander Wood intended doing, and decline to pass any further comments upon the proposed Bill until it was brought before Parliament.

After a few remarks from Dr. QUAIN and Mr. COOPER,

Dr. ANDREW WOOD proposed an amendment, which was of such extreme length that Sir DOMINIC CORRIGAN objected to its reception.

The PRESIDENT ruled that the objection of Sir Dominic Corrigan must stand, as the amendment contained not only a series of propositions, but was the embodiment of a long speech.

The amendment was therefore refused to be received.

Dr. STURRAR said, there was one resolution he should like to propose before the final vote on the Bill was taken, which was in reference to the nefarious system of imposture carried on by the quacks, and the difficulty experienced by private individuals in prosecuting them. With a view to obviate this difficulty in future, he proposed, "that in any future Act provision should be made for instituting prosecutions by a public prosecutor, or other authorized functionary, instead of leaving the enforcement of the law to the voluntary action of individuals." This was seconded by Dr. SMITH, and unanimously agreed to.

Dr. BENNETT then moved, and Mr. HARGRAVE seconded, "That the Report of the Committee be adopted." For this motion 8 voted for and 8 against, the rest declining to vote. The Report therefore stands *in statu quo*.

Upon this Sir DOMINIC CORRIGAN proposed, and Dr. SMITH seconded, "That the President be requested to write to the Lord President of the Council, to the effect that, on the receipt of his lordship's communication of the 14th May, it was referred to a committee of the General Council appointed to consider the amendments of the Medical Acts; that the enclosed was the report submitted to the Council by the said Committee, but not as a whole adopted; but that the following resolutions were adopted:" agreed to.

Dr. BENNETT next moved "That the President and Executive Committee shall be authorized (if it shall appear necessary) to confer with the Government upon the subjects referred to in the Lord President's communication, and report the results of any such conference to this Council at their next meeting." This was seconded by Sir DOMINIC CORRIGAN, and carried.

The Report of the Committee on communication from Dr. JOHN HARLEY, Mr. COURTAULD, Dr. MACLOUGHLIN, and Dr. EDWARDS CRISP was next read, and ordered to be entered upon the Minutes. This Report stated that the matters referred to in the several communications did not fall within the province of the Medical Council. A similar answer to that given to Dr. Crisp in 1868 being again agreed upon, "The adoption of the Report of the Committee on returns from the licensing bodies of professional examinations and their results, and on the registra-

tion of students for the year 1868," was next agreed upon, and the following motions were agreed to by Dr. ACLAND:—

"That it be referred to the Executive Committee to consider with Mr. Ouvry the resolution of the Council with respect to the Report on State Medicine, and to take the steps necessary for carrying the resolution into effect."

"That the State Medicine Committee be re-appointed, and that the Report and Appendix on State Medicine be forwarded by the Committee, with the resolution of the Council thereon, to the Licensing Bodies and persons interested in the subject of State Medicine, requesting their observations thereon; and that the Committee present those communications, or a digest of them, to the next meeting of the Council."

The following Report of the Pharmacopœia Committee was then agreed to, and the Committee re-appointed, consisting of Dr. Christison, Dr. Sharpey, Dr. A. Smith, and Dr. Quain:—

"The Pharmacopœia Committee appointed by the Resolution of the Council, July 7, 1868, have to report that in accordance with the directions of the Council, they caused to be printed a slip copy of certain slight typographic and minor errors, which required correction in the Pharmacopœia of 1867. These slips were inserted in the unsold copies of the Pharmacopœia, and were issued to those who had already purchased copies of the work. A re-issue of the Pharmacopœia having since been required, those slight corrections have been introduced into the work, which is in all other respects identical with the copies previously issued. The Committee have engaged during the past year the services of Dr. Redwood, in watching over the progress of pharmacy, and in making record of such corrections and additions as would hereafter facilitate the preparation of a future edition of the Pharmacopœia. In that duty he has received various suggestions from the members of the Committee, and has submitted a Report to the Committee which has been reserved for future use. He has, however, been requested to bring before the Pharmaceutical Society the substance of his first two reports to this Committee, with a view to the discussion of points needing inquiry or investigation."

"The Committee have expended £30 from the sum of £50 placed at their disposal. It is recommended that the Committee be re-appointed, and that the sum of £50 be again placed at their disposal for the ensuing year.

"R. CHRISTISON, *Chairman*.

July 8th, 1869."

Three communications were then read, the first of which caused considerable merriment, Dr. SMITH suggesting that shortly the dentists and others would make application to be represented upon the Council:

1.—A memorial which had been presented by the Obstetrical Society of London to Her Majesty's Secretary of State for the Home Department.

2.—A memorial from the Medico-Ethical Association of Manchester on the subject of the Medical Act.

3.—A communication from the President and Council of the Royal College of Surgeons of Edinburgh.

The remainder of the business consisted chiefly in passing the customary votes of thanks to the President, the Treasurer, the officials, &c., and the Council concluded the Session of 1869 in the usual manner.

Correspondence.

DR. EWING WHITTLE v. DR. C. R. DRYSDALE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps you will allow me, as a member of the London Dialectical Society, to say a few words in reply to Dr. Whittle. That gentleman (MEDICAL PRESS AND CIRCULAR, June, 1869) is very indignant because Dr. Drysdale does not enter the lists with him. But he should recollect that as he has thrown down the gauntlet, his opponent ought in fairness to have the choice of weapons. If he can so far forget Doubleday as to put aside such insinuations as that "the Malthusians of to-day disregard *in toto* the appeal to the authority of revelation, if they even admit an overruling Providence," and the use of such terms as "disgusting," "vile," &c.,—Dr. Drysdale will, I am convinced, be glad to discuss the matter with him.

Opponents of practical Malthusianism may be divided into two classes:—1st, Those who consider any restraint on popu-

lation an interference with the will of God; and, 2nd, Those who hold that poverty is caused by the method of distribution of wealth at present established. In answer to the first it may be remarked that they ought in consistency to denounce lightning-conductors, vaccination, chloroform, life-boats, and all other remedies for natural evils. Indeed, the prevention and cure of syphilis are often resisted on this very ground. The second class, the communists—to which class Dr. Whittle, judging by his denunciation of what he calls our "system of land and capital monopoly," seems to belong—have, I must acknowledge, shown an acute sense of the fitness of things in selecting Doubleday's theory as a foundation on which to build one of their numerous castles in the air. That theory asserts that the fertility of human beings varies inversely as the quality and quantity of their food. According to this, the early colonists of the United States, who had plenty of good food, ought to have multiplied very slowly; whereas the very reverse was the case. The fact is, Doubleday mistook cause for effect. The people are not numerous because they are poor, but they are poor because they are too numerous. It is true that poverty tends to reproduce itself; but that is because it makes its victims reckless, and dependent on sensual pleasures. If Dr. Whittle will read the economical works of Mr. Mill and Mr. Thornton, he will find abundant recognition of this fact. It may also be true that a plethoric condition caused by over-feeding is unfavourable to fecundity; but, if so, this must be considered as equivalent to disease, and resolves itself into what Malthus would call a positive check to population.

In conclusion, allow me to say that it must be evident to all candid persons that Dr. Drysdale is actuated in this matter by no other feeling than pure love of the human race. This being so, he may well treat with a contemptuous silence imputations of immorality and impiety—imputations which fall very harmlessly on the holders of a doctrine first propounded by one of the purest divines who ever graced the Anglican Church, and advocated by such men as Archbishop Whately and Dr. Chalmers. Denunciations of this kind are apt to remind us that Christ was put to death as a blasphemer and Socrates as a corrupter of youth. At all events, they are out of place in a scientific discussion; and are nothing short of insulting when addressed as arguments to a noble, generous, and learned profession.

Very respectfully yours,
J. H. LEVY.

TREATMENT OF FRACTURE OF THE THIGH BY THE WEIGHT AND PULLEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—My attention having been called to the correspondence on this subject, which has lately appeared in the MEDICAL PRESS AND CIRCULAR, I beg to refer to the fact, that, in or about the year 1852, I forwarded to the Surgical Society the particulars of a very remarkable case treated by me on this plan, and, to the best of my recollection, my report appeared in some of the subsequent numbers of the *Dublin Medical Press*.

The case and its results were so instructive that I shall here briefly recapitulate the leading features of it.

In or about the date referred to, a collier received a simple fracture of the femur.

Severe diffuse erysipelas, of the character known as diffuse "phlegmonous erysipelas," shortly afterwards seized on the entire limb, imperilling the life of the patient. All appliances for the purposes of extension and counter-extension had necessarily to be utterly abandoned, and every effort directed toward saving the life of the patient. By the time that the state of his health and the condition of the limb were such as to permit of the application of any apparatus for the adjustment of the fracture, shortening had (*unavoidably*) taken place to a great extent, and *union* of the overlapping fragments had proceeded so far, that in the unhealthy and disorganised condition of the soft parts, any attempt at rectifying the deformity which had occurred was utterly out of the question; and he left hospital, after a sojourn of some months, with the limb shortened a couple of inches.

In the course of many months afterwards, this man fell, and broke the same thigh again. He now came under my care in Kilkenny County Infirmary. He at once most earnestly implored me, if at all possible, to restore the limb to its original length. I was disposed at first (considering the amount of

deformity, and the time which had elapsed) to regard the proposal as chimerical. However, I tried the weight and pulley; he bore it with great fortitude, and the result was that he left hospital with the limb, to his great delight, restored to its full original length, and free from all deformity.

Owing to the confirmed contraction of the powerful muscles, which had adapted themselves to the shortened condition of the femur, a much heavier weight had to be used than is requisite under ordinary circumstances, and much greater fortitude was required on the part of the patient; the result was most remarkable.

It matters little to science or mankind who was the originator of this plan. The question of "*priority*" seems to me of little moment. The great question at issue would seem to be, is the plan useful and effectual, and that it is so seems established by the fact of its being advocated by so many practical surgeons, most, if not all of whom, were probably "inventors," so far as originating it for themselves. In this sense, I invented it in 1852, never having seen or heard of the plan before. Dr. David Jacob invented it for himself in 1856; Sir Philip Crampton, probably also, in 1846. But Dr. Smith, of Donaghmore, has taken the wind out of all our sails by showing that Dr. Daniell, of Georgia, U. S., recommended it so far back as 1829.

In my case I effected two points of extension, one by broad adhesive straps above the knee; the other, by similar means, attached to the calf of the leg and forming a loop below the foot. By this means great relief was afforded, by alternating the point of extension, and especially by relieving the traction on the ligaments of the knee joint. But in this particular case an unusually heavy weight was required to overcome the permanent contraction of the muscles.

I was much amused last winter by seeing the same plan of extension which I had used in 1852, and which others, no doubt, have used before and since, lauded in some of the journals as the invention of an American Professor, and dignified with the high-sounding title of "*Pancoast's stirrup*." If there be any truth in the maxim, "*Cælum, non animus, mutant, qui transmare currunt*," it seems hard to divine why that should obtain credit as the assumed invention of our transatlantic cousin which met no praise or recognition as the frequent practice of Irish surgeons. But, Dr. Smith has shewn that Professor Pancoast, as well as ourselves, must yield the palm of *originality* to his countrymen, Dr. Daniell and Dr. Dugas, who respectively advocated the plan in 1829 and 1854. I shall only add, "*Palmam qui meruit ferat*;" and am, dear Sir,

Yours very truly,

ZACH. JOHNSON, A.M., T.C.D., F.R.C.S. &c.

Kilkenny: 30th June, 1869.

PROSTITUTION AND ITS CAUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of Mr. R. J. Kinkead criticizing the able and philanthropic paper of Dr. Charles R. Drysdale, the accomplished and well-known London physician, contains remarks which demand reply. My quotations from the letter in question will suffice, without occupying your columns by comment.

Mr. Kinkead states "*prostitutes are well fed and clothed*"—"are exposed to no hardships or privations,"—"that many may be seen in the day standing behind counters who at night act the harlot." The latter statement is as slanderous upon the young women of our times, employed in shops and warehouses, as his remarks are foolish and untrue. Mr. Kinkead's experience of the subject upon which he writes, has not been the result of observation gained outside the College library, or Dublin has deteriorated within the last few years.

I am in many instances unable to comprehend how Mr. Kinkead's graphic history of prostitution during early periods affect the arguments advocated by Dr. Drysdale; on the other hand, in many instances I believe it confirms them.

"The only true way for the abolition of prostitution," recommended by Mr. Kinkead, is suggestive of the fact that the Irish Church labours under a loss so long as Mr. Kinkead is not enrolled among its members.

I am, Sir, your obedient servant,

J. WARING CURRAN.

PURCHASE OF HOSPITAL OFFICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leader on this subject induces me in the first place to beg your readers to peruse the report of the discussion, and my reply, which I have published through Fainin, and of which your pages gave them no opportunity of judging. You impeach my statement of facts, without offering any specific refutation; I therefore repeat a few of my charges, which, if untrue, can be denied, as all the parties are living. In one hospital the following transactions occurred:—1. An officer dying, his successor paid £750, all of which was divided amongst the five medical electors. 2. A retiring officer, previous to his resignation, voted for a gentleman who paid him a large consideration sum. I freely acknowledge that the purchaser was a highly qualified surgeon, just such a man as election by merit would have promoted. 3. According to an unrefuted letter from Mr. O'Grady (*Saunders*, August 1, 1868) a vacancy was filled at the same meeting at which it was declared, notwithstanding his objection that he "had only then learned the names of the candidates." There were then four applicants, of 15, 8, 4, and 1 years' standing respectively; there is usually but one who has completed arrangements.

In another hospital three surgical vacancies arose within a year. Many first-rate men who desired the office did not apply, believing the election had been forestalled; but, according to your Journal, the candidates included six Fellows of the College of Surgeons (four of them being amongst its leading officers) and a new Licentiate. The last-named was elected on the third occasion, and had received an almost effectual support on the second, and even on the first election. The allegation that he bought the support of one elector, if unfounded, remains uncontradicted, and is currently believed. To particularize and characterize more fully the purchasers would be cruel, and, for most of your readers, would be unnecessary.

I must demur to your proposition that the medical men who founded "the City of Dublin Hospital, and what we may call proprietary hospitals," have as clear a right to sell their shares as a railway shareholder, so long as these places for the cure of the sick are supported by public taxes and subscriptions. The selection of men of proven competency has been a good feature in the City of Dublin Hospital, but the want of £800 has excluded men who might, perhaps, be still more able.

In your last paragraph you impugn my taste and my loyalty to my profession. In reply to this, I must observe that the competition for hospitals was running downwards as regards merit, upwards as regards price. Juniors, full of talent, but wanting money or interest, were losing hope; students were indignant at the selection of their teachers by purchase; and the interests of the poor were threatened; and the *Lancet* was calling attention to these evils. I knew not who suggested or wrote the articles in that journal; but, in the interests of the poor, the profession, and those junior members of it who chose to rely on their merits alone, I felt called on to set forth the electoral systems of all the hospitals, and all the more as the blameless were condemned with the faulty. My paper and my future efforts will, I trust, lead to reform; and meanwhile my conscience acquits me of having acted through resentment or other unworthy motive.

I must further ask you, by whom are reforms to be effected in any profession whatever? If they are proposed by members of the profession, the reformers are met, as I am, by the cry that they are disloyal to their brethren. If the reforms are proposed by a man outside the profession, he is met, as Mr. Shaw was, with the cry that he is talking upon a subject of which he must needs be ignorant.

I have few comments to make on Mr. Wilmot's gentlemanly and deductive letter. If he will study the *concours* as described in several articles in the *Medical Times and Gazette*, 1867, and the medical officers' recommendation system as detailed in the University College Calendar, he will be convinced that by these modes of estimating merit all unworthy influences—pecuniary, personal, political, or sectarian—are excluded as completely as possible. Sir D. Corrigan and Mr. Wilmot defend the purchase system as if it were a safeguard against election from personal or political motives; now I attacked it as, besides corrupt in itself, especially injurious in promoting the success of those who seek hospital appointments on those very grounds. Mr. Wilmot refers to my opinion of the Dublin school. Let me reproduce the whole passage:—"In the

Dublin Hospitals, where nepotism or purchase prevail, a young man is at once thrust into the highest office, and although he with ability often becomes an expert practitioner, he just as often becomes a mere routinist, owing to the amount of important practical duty forced upon him. In this way I would account for the fact that the Dublin school, although eminently sound and practical, is remarkably barren of discovery or scientific research. I would then urge the appointment of assistant physicians and assistant surgeons to all the hospitals." The Dublin Hospital physicians and surgeons are as able as those of any other city in the treatment of disease, but they have not enlarged the bounds of medical knowledge by working at such useful subjects as urinary pathology, morbid histology, experimental therapeutics, or the improvement of surgical apparatus, as earnestly as they would have done had the first seven years of their hospital service been spent as assistants, not equals of their seniors. Men thus trained should alone obtain physiciancies and surgeoncies; and, as after twenty years' service in these last named positions they would cease to benefit themselves and to serve the poor as efficiently as younger men, they should be advanced to the consulting ranks. Mr. Wilmot remarks, "no system can create genius, and none retard its progress;" an argument which may be regarded as a compendious way of justifying bad systems in every department of human action. I quite admit that a good system will not create genius, but it may foster it. As to the second part of the assertion, I hold it to be entirely false. The fact which misleads Mr. Wilmot into this view is probably this, that under no system, however bad, provided only it is such as society can allow to exist, can all men of genius be excluded from success. A great many, however, are, and the worse the system the more it excludes.

Yours truly,

E. D. MAPOTHER.

125, Stephen's Green, July 17.

RED TAPE.—HOW NOT TO DO IT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I lately saw that copies of the "Nomenclature of Disease" were to be distributed by Government to the profession. I concluded that medical institutions, where registers and records of disease are kept, ought to be supplied at least as soon as any other claimants. Wishing to co-operate with the authorities, but not knowing where to apply for it, on the 5th July I addressed a letter to the Secretary of State for the Home Department begging that a copy might be sent to the Kilkenny County Infirmary, of which I was an officer. The reply which I received appears deserving of publication, as a specimen of Routine and "Red Tape."

(Copy.)

"Whitehall, 8 July, 1869.

"SIR,—I am directed by Mr. Secretary Bruce to acknowledge the receipt of your letter of 5th inst., applying for a copy of the 'Nomenclature of Disease,' for the use of the Kilkenny County Infirmary; and I am to inform you that the Secretary of State has no copies of such work for distribution.

"I am, Sir, your obedient servant,

"A. F. O. LIDDELL.

"Z. Johnson, Esq., County Infirmary,
Kilkenny, Ireland."

To have informed an applicant, anxious to co-operate with the authorities in furthering the cause of medical science, where he ought to apply for a work espoused by the Government and to be had only from them, would seem to be a stretch of condescension not to be thought of by the well-paid Red-Tapists of the Home Office.

Dear Sir, your obedient servant,

ZACHARIAH JOHNSON, A.M.T.C.D., F.R.C.S.,
Kilkenny.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a contribution to the statistics of operative surgery, I beg to submit the following cases which have occurred in my practice.

Primary.

•Two amputations at surgical neck of humerus, circular; successful.

One amputation at junction of lower and middle third of humerus, circular; successful.

One amputation of hand, cutting through the metacarpal bones about their middle flap; successful.

Secondary.

One amputation, thigh, for long-standing disease of knee-joint at junction of lower and middle third; circular. Lived for seven months, disease setting in in the stump two months after operation.

Portlaw.

JAMES MARTIN.

Medical Cleanings.

CAMPHOR AS A PREVENTIVE OF OXIDATION.

Mr. George Wellborn (*Journal of Applied Chemistry*) finds that a small lump of camphor placed in a bottle of recently crystallized protosulphate of iron preserves it from oxidation, the salt remaining as a transparent solution after it had been kept three months. If the odour of camphor acquired by the salt is objectionable, it may be exposed awhile before using, or it may be removed by alcoholic washing and dried.

GUYOT'S CONCENTRATED TAR SOLUTION.

Dr. Jeannel (*Journal de Pharmacie*), from an analysis of "Guyot's Concentrated Tar Solution," has deduced the following formula for its reproduction: bicarbonate of soda, 22 parts; tar (from wood), 25 parts; water, 1,000 parts. Macerate together for eight days, shaking the mixture several times each day.

This preparation, diluted with sixty or eighty times its volume of water, forms a clear tar-water for internal administration; in a less diluted condition it is also employed as a lotion.

SYRUP OF IODIDE OF IRON AND ITS PRESERVATION.

M. Jeannel (*Journal de Pharmacie*) approves of the following combination for the manufacture of a solution of iodide of iron which shall remain unchanged by exposure to the air: iodine, 8·2 parts; iron filings, 4·2 parts; distilled water, 20·0 parts; honey, 70·0 parts; tartaric acid, 0·5 parts. Mix the iodine, iron, and water in a flask, and when combination is complete, filter the green solution, and add the honey and tartaric acid. The product will contain 10 per cent. of iodide of iron.

He also observes that the addition of one five-thousandth part of tartaric acid to syrup of iodide of iron which has become bad, renders it clear, and, at the same time, notably diminishes its inky taste.

TUBERCULOSIS OF THE CHOROID.

In the session for Dec. 9th of the Berlin Medical Society, B. Fränkel (*Boston Med. and Surg. Journal*) reports two cases where meningeal tuberculosis was diagnosed by the aid of the ophthalmoscope. In the first case, that of a girl of six years, vision and consciousness remained unimpaired until death, and no subjective symptom that could prove the existence of meningitis was observed. The second case, in a boy of eight, was so similar, that the physician was enabled from the appearance of the eye alone, to establish the diagnosis, which otherwise would have been entirely uncertain.

Hyperemia of the retina was observed, and close to the papilla a white roundish spot of about one-sixth the diameter of the latter. Three other such spots were afterwards seen, all fully exhibiting the characteristics of tubercles of the choroid. For four weeks the patient made no complaint whatever of his eyes; he read, wrote, and saw as usual, had neither sparks before his eyes, nor photophobia. Six weeks after the diagnosis of general tuberculosis was made, appeared the first distinct symptoms of tubercular meningitis.

UNGUENT FOR BRONCHOCELE.

Prof. JAMES R. WOOD, of New York, extols the following formula as an ointment in bronchocele and other glandular tumours:

R Ung. stramonii	ʒ ij.
Ext. conii	ʒ ij.
Iodid. potassii	ʒ ij.
Iodini	gr. x.
M. Ft. unguent.	

POISONING BY ARNICA.

A CASE occurring in a woman of thirty-three years of age, is reported in *Schmidt's Zahnbucher*. She had drunk two glasses

of infusion made from a large handful of the leaves. The symptoms of poisoning lasted seven days, and the patient was not quite well till the 12th. The prominent symptoms were violent vomiting, intense headache, choleric diarrhoea, with very severe gastro-intestinal colic, followed by collapse, cold extremities, and remarkable depression of the pulse. The treatment consisted principally of the use of extract of the baine and of morphia.

PHENIC ACID IN SYPHILIS.

Dr. MINTEFORTE (in the Italian *Journal of Venereal Diseases* &c.) recommends the application to syphilitic ulcers of a solution of phenic acid in water, five parts to 100. Dr. Fidele de Fieri extols the deuto-phosphate of mercury, one grain a day continued for two months, in tertiary syphilis.

Medical News.

Two coloured physicians of Washington, complained that the Medical Society of the District of Columbia will not admit them as members, after having granted them licences to practise.

THE Director-General of the Medical Department of the Navy, Dr. Armstrong, paid his first official visit to Chatham on Wednesday, the 14th inst., and made a minute inspection of Melville Hospital, and subsequently visited the dockyard.

WILLS AND BEQUESTS.—Mr. James Sturm, of North Villa, Hampstead, has bequeathed a legacy of £500 to the National Lifeboat Institution, and directs that a boat should be named "James Sturm" and be employed on the northern coast of Scotland. He bequeaths to the senate and governing body of the University of Aberdeen a sum of £2,000 to found two scholarships for five years, to be called "James Sturm's Scholarships," for natives of Mortlach, of the age of fifteen years, who had been taught in the parish school of Mortlach; also £500 for the education of females of Mortlach in the principles of the Established Church of Scotland; and a further sum of £500, a portion of the interest of which is to be expended for the relief of infirm poor persons of the village of Duftown. There are the following contingent charitable bequests, payable on the discharge of a claim or debt due to his estate—viz., to the Foreign Missions of the Established Church of Scotland, the Society for the Propagation of the Gospel in Foreign Parts, London Missionary Society, Royal Society for the Protection of Life from Fire, Queen Adelaide's Dispensary, City of London Truss Society, British Orphan Asylum, and King's College Hospital, each £500.

FEMALE MEDICAL EDUCATION IN SWEDEN.—It is announced that the Swedish Government purposes next year to establish a Medical College at Gothenburg, to ladies not under seventeen years of age may be admitted to a complete course, lasting three years, with clinical and anatomical lectures, &c.; the graduates of this College being allowed to establish themselves as physicians all over the kingdom. The practice of midwifery is already almost entirely in the hands of women and institutions for teaching it in all its branches have been long established.

CHARING-CROSS HOSPITAL.—The prizes to the students of the medical school attached to this hospital were distributed in the presence of a large number of ladies and gentlemen interested in the welfare of the institution. Professor Owen presided. The following prizes were awarded:—The Governors' clinical silver medal to Mr. Kidd; in the class of botany, a silver medal to Mr. Noakes, and certificates of honour to Mr. Leigh, Mr. Drake, and Mr. Graham; in the class of materia medica and therapeutics, a silver medal to Mr. Atkinson, and certificates of honour to Mr. Leigh and Mr. Noakes; in the class of midwifery, a silver medal to Mr. Towl, and a certificate of honour to Mr. Conolly; in the class of pathology and morbid anatomy, a silver medal to Mr. Hyde, and a certificate of honour to Mr. Conolly; in the class of forensic medicine, a silver medal to Mr. Conolly and a certificate of honour to Mr. Rix; in the class of practical chemistry, a silver medal to Mr. Leigh, and a certificate of honour to Mr. Noakes; in the class of senior anatomy, a silver medal to Mr. Leigh, and a certificate of honour to Mr. Walker; in the class of junior anatomy, a bronze medal to Mr. Routh, and a certificate of honour to Mr. Taylor; in the class of chymistry, a silver medal to Mr. Lea, and certificates of honour to Mr. Taylor and Mr. Whitlam; in the class of senior medicine, a silver medal to Mr. Gosse, and a certificate of honour to Mr. Towl; in the class of junior medicine, a

bronze medal to Mr. Gravelle, and a certificate of honour to Mr. Leigh; in the class of senior physiology, a silver medal to Mr. Noakes and certificates of honour to Mr. Drake and Mr. Burroughs; in the class of junior physiology, a bronze medal to Mr. Chittenden; in the class of surgery, a silver medal to Mr. Hyde, and certificates of honour to Mr. Towt and Mr. Kidd.

A CLEVER LUNATIC.—The intellectual activity of a certain class of lunatics is curiously illustrated in the report on the lunatic asylums in Ireland which has lately been printed and laid before Parliament. A man named Joseph Langfrey escaped from the Central Asylum with two other patients, none of the party being looked upon as lunatics by the medical officers, although confined there as criminal lunatics. Mr. Langfrey was the leader of the fugitives, and is described as being of an extraordinarily clever and ingenious mind. He could do things quite beyond what men in general can perform, and his cleverness was even exceeded by his versatility. He was a good shoemaker, a tailor, a weaver. He made from a scrap of iron a key by which he could open the door of his division. He put together a wooden sewing-machine of his own contrivance, with which he made clothes for himself; and his mind just before his escape seemed so intent on improving this machine that there was little apprehension of his attempting to escape. His career, it is stated, before he came to the asylum was most extraordinary. He had been in the British army, in the French army, and in the French navy; and had been in British, German, and Russian prisons. He had a fair grammatical knowledge of French, knew something of German, and was completely self-taught; his age, although he had passed the various phases of existence above described, was only twenty-seven. He spoke well and reasonably, the great defect in his character being a fickleness of purpose. He had that rambling disposition that is never sated with travel and adventure; and if his principles were good and upright he would in all probability have had a distinguished career in life. Langfrey was, in fact, not unlike one of Ouida's heroes. No trace of him has yet been found.—*Pall Mall Gazette*.

NOTICES TO CORRESPONDENTS.

DR. DAY, Torquay.—We are obliged for your note, but cannot possibly comply with the terms proposed.

DR. EWING WHITTLE, Liverpool.—Your paper on "The Population Question" is to hand, but owing to its length is unavoidably left over to our next. In future you would greatly oblige by sending in any except very short communications before Monday, as the Journal is made up for press on the evening of that day in order to secure the postage of subscribers' copies on the following evening.

COMMUNICATIONS, Enclosures, &c., received from Dr. Day, Torquay; Dr. Patrick Heron Watson, Edinburgh; Dr. Rumsey, Cheltenham; Dr. Pearson, Kensington; Dr. Pearce, Bodmin; Dr. Thos. Matthews, Manchester; Dr. Annandale, Edinburgh; Dr. Mapother, Dublin; Mr. Walter Rivington, London; Dr. Palfrey, London; Dr. Maunsell, Dublin; Dr. Ewing Whittle, Liverpool; Dr. Johnson, Kilkenny; Dr. Dudley, New York; Dr. Ross; Mr. Yearsley, London; Mr. Hamilton, Mr. W. L. Scote, London; Dr. Purdon, Belfast; Dr. Gordon, Portsmouth; Dr. Collard, Bishopwearmouth; Mr. Newton; Mr. Clarke; Dr. Henry; Dr. Burrows; Mr. Stewart, Edinburgh; Dr. Williams; Mr. Tichborne, Dublin; Dr. Stoker, Dublin; Dr. Cleland, Galway; Dr. Lamprey, Portsmouth; Dr. Willan, Haxey; Mr. Shinkwin, Cork; Dr. Waring-Curran, Manchester; &c., &c.

THE NOMENCLATURE OF DISEASES.—"TRICHINA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Looking the other day into a recent medical lexicon, I met with the term *trichina*, as employed to designate the microscopic hair-like animalcule which infests the muscles of people who have fed for a long time on mealy pork. Will you allow a non-medical man to point out the violation of correct nomenclature with regard to this topic?

First of all, *trichina*—and it is exactly so in the book to which I allude—is manifestly a false quantity, for the adjective *trichinos*, formed from *trichos*, the genitive case of *thrix, hair*, has its penultimate short; and *trichina*, being the neuter plural, would simply mean *hairy things*. Now, these microscopic worms are not hairy, but as *fine as hairs*, or, *curled like very fine hair*. If so, we should perhaps call this creature *trichoid, hair-like*, just as we say *typhoid*.

I conceive that, strictly speaking, we might designate the worm, *trichinia*, making in the plural *trichiniae*, and we might say, "this patient has *trichiniae*," or it might be *trichinides*, from *trichinis*, which would also be a correct form, and would follow the analogy of *ascarides*, by which we designate *thread-worms*. Then, why not *trichinides* for *hair-worms*?

As to the disease itself, it strikes me that the correct form would be *trichinosis*, just as we have *sycosis, tuberculosis*, and the like. This would violate no rule of the nomenclator's art, and would easily convey its own meaning. But against *trichina* with *i* long, which is abominable, and *trichina* with *i* short, which is unclassical, I must be allowed to protest.

If these remarks are of the least value, please let your medical readers have the benefit of them, and oblige your occasional reader,

Queenborough, July 17, 1869.

Deaths.

BURNSIDE.—On the 7th inst., at Delaune road, Kennington Park, Matthew Burnside, Surgeon R.N. (1st July, 1813), retired list, aged 74.

CRANKE.—On the 2nd inst., R. Cranke, L.R.C.P.Ed., L.R.C.S.Ed., of Ulverstone, Lancashire, aged 29.

FROYSSELL.—On the 14th inst., at the residence of Mr. Henry Gibbons, Stafford street, Wolverhampton, Joseph Froyssel, M.D., formerly of Willenhall, Staffordshire, in his 63rd year.

ROBERTSON.—On the 10th inst., at Woodside place, Glasgow, G. Robertson, M.D.

SNATH.—On the 7th inst., at Boston, Lincolnshire, Frederick Snath, B.A., M.D., in his 63rd year.

STEPHENSON.—On the 14th inst., at Mile-end road, James Stephenson, M.R.C.S., L.S.A., aged 42.

WHITFIELD.—On the 7th inst., Henry Whitfield, M.R.C.S.E., of Ashford, Kent, aged 63.

LIQUOR CARBONIS DETERGENS.

THIS Preparation has now established itself among the leading Members of the Profession, not only as an unfailing remedy for indolent and putrescent sores of every description, but also as a highly useful and effective application in cases of recent wounds, amputations, &c. In old-standing cases it destroys the diseased parts, and protects the newly-formed products and tissues from fermentation; while, in cases of a recent character, it prevents the formation of pus, and induces immediate or rapid healing. It contains a large percentage of that most powerful and useful agent, *Carbolic Acid*—not, however, in an isolated form, but in its natural state of combination with Benzine, Naphthaline, and the various active principles of COAL TAR. It is therefore free from the capital objection which may be always urged against the use of highly concentrated or intensely caustic medicines, as well as from the practical danger which often waits upon their operation. In fine, it subserves all, and more than all, the uses of *Carbolic Acid*, with this additional and most essential recommendation, that it may be exhibited without the smallest risk where experience has shown that *Carbolic Acid* is inadmissible or unsafe.

Sold only in Bottles containing 16 Fluid Ounces, at 4s. 6d.; 43 Ounces, 11s.

PURE COAL TAR SOAP,

REGISTERED AS "SAPO CARBONIS DETERGENS."

This Soap is compounded from our "Liquor Carbonis Detergens," and is very highly recommended by the leading Medical Journals. See *The Lancet*, Dec. 22, 1866; *Medical Times and Gazette*, Jan. 19, 1867; *British Medical Journal*, Jan. 26, 1867.

Sold Retail by Chemists in Tablets at 6d. and 1s. each; and direct from the

Proprietors, W. V. WRIGHT & COMPANY, Manufacturing Chemists & Wholesale Druggists, SOUTHWARK STREET, S.E., (REMOVED FROM 11 OLD FISH STREET).

MARRIAGE SETTLEMENT POLICIES.

"By affording an easy and inexpensive means of making provision for families, if (the Norwich Union Life Insurance Society) will confer a substantial benefit upon society."—*Law Journal*, Dec. 6.

For Prospectuses, showing the mode by which this inalienable provision may be made for a family, either before or after marriage, apply to the NORWICH UNION LIFE OFFICE, 50, Fleet Street, (E.C.)

PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES

OF BOTH SEXES,

MENTALLY AFFLICTED,

TUEBROOK VILLA,

NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWE

THE LONDON SURGICAL HOME,

FOR DISEASES AND ACCIDENTS OF WOMEN;
for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. BAKER BROWN.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the LADY SUPERINTENDENT, Osanburgh place, Regent's Park, London.

T. & H. SMITH'S

CODEIA LOZENGES.

THESE LOZENGES have a remarkable effect in allaying Cough and Irritation of the Throat and Chest.

Prepared only by T. and H. SMITH and CO., 21 Duke street, Edinburgh, and 69 Coleman street, London; and to be had of any Chemist and Druggist, in Boxes at 1s. 1½d. and 2s. 9d. each.

CHLORODYNE, TOWLE'S,

continues to gain increased confidence with the Profession, on account of its known Composition and Uniform Strength.

2 oz., 2s. 9d.; 4 oz., 4s. 6d.; 10 oz., 11s.

LIQ. CHLORODYNII, expressly for Dispensing.

1 lb. bottles, 12s. ½ lb. ditto, 6s. 6d.

AND

LIQ. CHLORIFORMI CO. (vel) CHLORODYNE

Sine Ol. Menth. Pip.

2 oz., 2s. 6d.; 4 oz., 4s.; 8 oz., 8s.

A. P. TOWLE, MANCHESTER.

DINNEFORD'S FLUID MAGNESIA

Perfect in purity and strength.

"The Fluid Magnesia I obtained from you corresponds precisely with that of the 'British Pharmacopœia,' 1867, and is what the preparation should be."—Professor Redwood.

Sold in Gallon and Half-Gallon Jars for the use of the Profession only by all Wholesale Druggists, and by the Manufacturers,

DINNEFORD & CO., PHARMACEUTICAL CHEMISTS,
172, New Bond street, London.

JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remarks on the part of the Proprietor unnecessary.

To be had of all Wholesale Druggists.

SCOTTISH PROVIDENT INSTITUTION FOR LIFE ASSURANCE.

ANNUAL INCOME £250,000 0 0
ACCUMULATED FUNDS £1,500,000 0 0

The only Office which combines the benefit of participation in the
WHOLE PROFITS WITH MODERATE PREMIUMS.

EXAMPLES OF ANNUAL PREMIUM FOR ASSURANCE OF £100 AT DEATH
(WITH PROFITS).

Age 25	30*	35	40	45	50
£1 18 0	£2 1 6	£2 6 10	£2 14 9	£3 5 9	£4 1 7

* Thus a person of Thirty may secure £1,000 at death (with profits) for a Yearly Premium of £20 15s., which in the other Scottish Mutual Offices would assure £800 only.

Above 19,000 Policies issued. Subsisting Assurances, over Six Millions.

Reports explanatory of the Principles, with every information, may be had at the Office in Edinburgh, or at the

DUBLIN OFFICE: 16 COLLEGE GREEN.

WILLIAM WILSON, Secretary.

ALBERT LIFE ASSURANCE

COMPANY,

7 WATERLOO PLACE, PALL MALL, S.W.

LIVES ASSURED,

DISEASED AS WELL AS HEALTHY.

ABSOLUTE SECURITY POLICIES, UNFORFEITABLE, UNCONDITIONAL, and UNCHALLENGEABLE issued by the PRUDENTIAL ASSURANCE COMPANY (Established 1848), No. 62 Ludgate hill, London, E.C.; Branch Office, 7 King street, St. James's.

The Directors of this Company, in deference to an objection not infrequently urged by persons invited to assure, that the ordinary mode of life assurance is in their opinion defective or uncertain, by reason of the operation of the customary conditions, have resolved to promulgate the present tables, and to issue assurances under them which shall be absolutely unforfeitable, unconditional, and unchallengeable.

For the reason referred to, many persons hesitate or decline to assure on the ground that, in the event of inability or unwillingness to continue payment of their premiums, the assurance will become forfeited. To this class of the public the system now introduced will especially commend itself, being entirely free from all conditions of forfeiture on account of non-payment of premium, or from any other cause whatever; while at the same time it absolutely guarantees at decease, even when a default is made in payment of the premium, a fixed sum in respect of every premium paid, bearing the same proportion to the total amount assured as the number of premiums actually paid may bear to the whole number originally contracted to be paid. Besides this important advantage, every policy will expressly state what sum can at any time be withdrawn on the discontinuance of the assurance. The assured will thus always have the option of retaining either an ascertained fixed sum payable at decease, or, in case of need, of withdrawing a certain amount, according to the duration of the policy, such amounts being set forth on every policy, and rendering unnecessary any future reference to the Company on these points, as is the case with ordinary assurances. Creditors assuring the lives of debtors will appreciate this feature as one greatly protective of their interests, and it will likewise commend itself to bankers, capitalists, and others who are in the habit of making advances collaterally secured by life policies, as they can at any time learn, by mere inspection, the exact value, either immediate or reversionary, of a policy of this description. Every policy issued on this plan will be without any conditions as to voyaging, foreign residence, or other usual limitations. By this freedom from restrictions of all kinds, the objections before referred to will be entirely removed, and the policies will become at once positively valuable as actual securities.

In addition to the foregoing statement of advantages the number of premiums is strictly defined. The longest term provided for is twenty-five years, and the shortest five years, as shown by the tables. Thus, bankers, creditors, and others holding policies of this class as security, may always know the utmost amount they may be called upon to advance, so as to maintain the full benefit of the assurances—a matter of great importance where policies are held as collateral security.

It is only necessary to add that, as a consequence of the policies under these tables being unforfeitable and unconditional, they will also be unchallengeable on any ground whatever. They may, therefore, be applied to meet Absolute Security Policies.

The Prudential Assurance Company possesses an income of £200,000 a-year. Its position is unquestionable, and it obtains the largest amount of new business of any office in the kingdom;

Special agents wanted.

ON THE TREATMENT OF BUBOËS AND THEIR SINUSES BY MEANS OF CARBOLIC ACID AND SMALL VERTICAL INCISIONS.

By J. LAMPREY, M.B.,
Surgeon 67th Regiment, Portsmouth.

IN the Appendix to the Report of the Committee appointed to inquire into the pathology and treatment of the venereal diseases in 1867, it appears that among the troops serving in the United Kingdom in 1864, of the average strength of 73,252 men, there were 2,011 cases of bubo admitted to hospital. The mean daily sick of this disease amounted to 199.3, and the average duration of the cases under medical treatment amounted to 36.17 days per case. From this extract it will be seen that army surgeons have considerable experience in the treatment of this disease, indeed, they are seldom if ever without one or more cases in their hospitals, so that they are but too familiar with the length of time it invariably takes to heal a suppurated bubo, associated with sinuses leading to other buboës, occurring in a large proportion of cases of the soft suppurating syphilitic ulcer, as well as in cases of sympathetic bubo unconnected with syphilis. According to the practice commonly observed in the treatment of such cases the suppurated bubo was generally first freely laid open in its longest diameter, and subsequently the sinuses leading from it to other buboës were opened up by means of the director and bistoury. The agony and suffering of the patient while this was being done are too well known to require description, as we have all seen such cases and noticed how the strength of the patient was wasted by protracted confinement to his bed, while the process of filling up and cicatrizing the deep ulcers with undermined edges made by the incisions were accomplished.

The importance of a method which would expedite the cure of this disease, and at the same time save the patient the suffering from extensive incisions, cannot be over estimated; and, however much beneath our notice such cases may appear to be at first sight, none reward the care and attention bestowed on their treatment with better results. A bubo which, under the old method of treatment, might take months to heal, may be cured in a few days by a more judicious mode. The importance of making the first incisions in a particular direction, always taking care that the bubo has well suppurated beforehand, is much greater than what it would appear to be. If it is made in a line parallel with Poupart's ligament every movement of the thigh will keep the edges of the wound in a constant state of motion; whereas if it is in a vertical direction the motion of the thigh will disturb the coaptation of the sides of the wound much less. This does not appear to be sufficiently dwelt upon in works on surgery, on the contrary, the recommendation of one of the ablest surgeons, in a work just published, is that the bubo should be laid open by a free incision throughout its longest diameter, either horizontal or vertical to Poupart's ligament. (See "Erichsen's Surgery.") Bumstead, in his work on syphilis, states that Langston Parkes, an American surgeon, treats buboës by opening them in several points and injecting sulphate of zinc, and using a compress; in every case he succeeds in making a cure in a few days. He punctures the bubo with a grooved needle, and takes care that the walls of the abscess are not too thin. From my own experience I prefer, for the reasons stated, a vertical incision in the centre of the suppurated gland, just sufficiently large to allow the free escape of the collected pus; and from the experience of repeated trials, I find that by injecting a solution of carbolic acid, diluted to one in ten, into the bubo, it has the effect of preventing the formation of pus in the bubo sack, and causes the secretion of what would otherwise be pus, to become a clear and serous looking fluid. The injection is done by a common glass urethra syringe, the nozzle being inserted into the opening into the bubo. This causes some amount of pain at first, but it soon passes off. Care must be taken, however, that none of the solution gets on to the scrotum or on the skin of the thigh or nates,

as it acts as a powerful escharotic on some individuals. This accident may be easily avoided by sufficient carefulness. The injection should be squeezed out of the sack by using moderate pressure, and it need not remain in it longer than a few seconds. I prefer injecting on the day following the incision, as this allows the pus to be freely discharged and the bubo sack to contract somewhat. I repeat the injection after an interval of three days, applying in the meantime over the bubo a piece of lint wet with carbolic acid, diluted to 1:40, and covered with gutta percha tissue. The interval of rest is of importance, inasmuch as it allows the reparative process of nature to be developed, as, after all, it is this that heals and not the applications.

Should another bubo form in the vicinity, and a communicating sinus establish itself between them, or should the extremity of the sack of a bubo be found to extend into the inguino-scrotal angle or in an opposite direction, none of which are of uncommon occurrence, instead of introducing the director, and slitting up the sinus or bubo to its full extent, I find a better plan is to introduce a probe to the furthest limit of the sinus or bubo sack, and make a small opening in the integuments so as to allow the extremity of the probe to pass through; by doing this a course is made for a free current of the carbolic acid injection to pass through, and in a few days the healing process is more satisfactorily established than if the sinus was laid open throughout its whole extent. Why this should follow it is difficult to explain, but one sinus treated in this way will be sufficient to show that it has this effect.

Fig. 1.

Fig. 2.

By the aid of the illustration representing one of these cases and exhibited to the Society, it will be seen what a formidable wound I avoided making. In this case (fig. 1) I introduced the probe at *a* till it reached *b*, when I cut down upon its extremity till it projected; and in the same manner I introduced the probe at *a* and extended it to *c*, when I cut down upon it also; so that by injecting at *a* I was able to send the fluid through either *b* or *c*. In this case the man made a recovery in ten days after the first injection. Had this man been treated after the old method of free incisions, there would have been an undermined ulcer of the size and shape depicted at *d* (fig. 2), and a length of time would have elapsed before it would have granulated and filled up from the bottom. In five other cases I brought before the Society to exhibit the results of this mode of treating bubo, the same satisfactory results were observable.

In cases where the bubo has been allowed to remain in a state of suppuration for too long a period, when the integuments become thin and of a purple tint, and almost beyond hope of saving them from spontaneous rupture, I have found the use of carbolic acid injection and lotion of great service in the treatment, saving the integuments from sloughing or ulceration.

The cases of simple bubo which are opened in the proper stage of suppuration and treated with small vertical incisions and carbolic acid injections get well in a few days, unless when the opening assumes the character of the soft chancre which originated it, in this instance there is no help for it but to wait for the usual period for such a chancre to heal, though the original chancre which gave rise to the bubo has already healed, as it invariably is the case when once suppuration in the bubo has been fully established. Of the preparatory treatment of bubo with

the view of preventing the formation of suppuration, it is not intended to enter into any discussion here; but knowing how difficult it is for art to accomplish this object—if, indeed, remedies avail much—it is satisfactory to know that the treatment of the already suppurated bubo we can now successfully adopt, makes the resolution of buboes of little moment, comparatively speaking. Should fomentations and poultices be found of no use after a fair trial of them, the better plan is to expedite the suppurative process by directing the patient to walk about, if he can do so without causing pain or constitutional disturbance, and that no chancres should be in the way, otherwise there is no help for it but to continue poulticing till suppuration has fully taken place.

In cases where the contents of a bubo are found, on opening it, to be composed of an indurated glandular structure partially suppurated, the carbolic acid injection and lotion will only prove useful in suppressing the secretion of pus without influencing the induration; in these cases the mercurial vapour bath will be found most effectual in causing absorption of the morbid induration without injuring the system.

ON THE THERAPEUTICAL EFFECTS OF STEAM UNDER HIGH PRESSURE.

By WILLIAM BENNETT, M.D., Harrogate.

WE find very many chronic affections of the skin annually resorting to Harrogate as a last resource; many of these have run the gauntlet of both hospital and private practice with but temporary benefit, and many others seem to have resisted every local and constitutional treatment within our reach. When we can succeed, therefore, in any cases, by any means hitherto unused, it is a pleasing duty to call the attention of our professional brethren to these, in the hope that a more extended application of such means may tend to alleviate the sufferings of many, and place at our command a most powerful agent for good—viz., the use of the Steam douche under high pressure. I have selected a few cases, which strikingly illustrate the benefits to be derived from this line of treatment.

J. G., æt. about thirty-six, married, tall and well made, rather pallid, with an anxious countenance, but not suffering much pain, was admitted into the Harrogate Hospital. About two years previous to his admission he had been laid up with a sore on the inside of the calf of the right leg, which, he said, was caused by a boil which he irritated, and which gradually enlarged. For this he entered the Leeds Infirmary, and after a long sojourn there this ulcerated surface healed, but leaving a cicatrix of such a character as induced me to ask him if he ever had syphilis at any former period of his life; this he denied. The whole inner surface of the right thigh, from a little above the knee to about three inches below Poupert's ligament, now presented an immense ulcerated suppurating surface, with deep excavations and sinuous passages extending through the thickness of the skin down to the fascia. The borders of these excavations were swollen, shining, and of an unhealthy appearance. The portions of skin not yet involved had a dark bluish appearance, the ulcerative process going on underneath so as to engage those portions of the hitherto healthy skin.

He had been under treatment for a very long time, both in different hospitals and under different private practitioners; was put under all kinds of treatment, both constitutional and local, and from a small ulcerated spot at first it gradually reached its present extent, and now appeared as if there never had been any attempt at healing. He was sent to Harrogate, impressed strongly with the idea that the sulphur waters and sulphur baths would promptly restore him to health and strength. My first and important duty was evidently to improve the man's blood, and to give him a generous diet. He was now at head-quarters

for obtaining iron in its best form of administration, and I allowed him the free use of the sulphur baths, so as to alleviate the irritability of such an extensive ulcerated surface. He had tried a host of applications of a soothing kind, then both stimulant and astringent; and, to use his own words, every change seemed to do a little good, but no satisfactory progress had been made towards cicatrization. He had been put under a course of mercury previous to his admission into our hospital, but with no benefit; and I confess I began to despair of success in such an obstinate case.

The case began to improve a little; the general health seemed better, but the appearance of the ulcerated surface was little changed. What we gained by the soothing treatment of baths was lost by the increase of suppuration, and by the relaxation of the whole surface, and bandages could not be borne. It was evident I wanted a stimulant of such a nature as would increase the circulation of all the cutaneous vessels, allay the irritability of the exposed nerves by such an amount of heat and moisture as would not be followed by too great relaxation, and yet which would rouse the vitality of the part, and thereby set up a more healthy reparative process. I conceived that I possessed in the steam or vapour douche not only two of the properties which I required, but also when used under high pressure I knew I had the command of a very great quantity of electricity, not of very high tension, which, by proper management and regulation of the pressure, would give me a stimulant very different from any that had been before applied. Persevering steadily with the vapour douche, I had the gratification, in a very short time, of observing a great change in the appearance of the entire ulcerated surface. The whole limb became more comfortable to the patient; the suppuration was greatly diminished; the swollen borders of the ulcers were flattening down, and it was evident the process of absorption was going on rapidly. Suffice it to say, after a residence in the hospital of about two months, I had the pleasure of dismissing this patient, capable of moving about without suffering, freed from all discharge from this extensively diseased surface, and cicatrization going on rapidly; and, after a month's residence at home, he was able to take a situation as toll-keeper on one of the southern roads in this county. I lost sight of him for more than a year, when I heard he died of typhus fever.

The case was altogether a remarkable one; it was supposed by those who treated it to have had a syphilitic origin. Appearances were strongly in favour of such an opinion, but it bore a very great resemblance to a former case of Radesyge exedens, or Norwegian scurvy, described by Dr. Hjort, and represented by Alibert and Willis as under the Tubercula. After J. G.'s death I found that a sister died of consumption who was unmarried, and who had this disease on one of her thighs. Whether of a syphilitic origin or not, it was very evident that the steam douche under high pressure removed this obstinate affection.

We meet with many cases where we can have no doubt of the existence of a syphilitic taint. In many such we find the lower extremities the seat of very troublesome ulcerations; the skin, particularly of the calf of the leg, becomes thickened, hard, and immovable; the circulation is much impeded, and motion rendered painful. It is very difficult to effect the healing of these burrowing ulcers, for pressure by bandages will not always be borne. Warm baths give but temporary relief; and under almost any treatment we fail in making the integument pliant and moveable under the fingers. In these cases I have found the vapour douche most beneficial. It produces comfort and ease, and in a short time the patient finds that he can take walking exercise with less difficulty and less pain; the indolent ulcers put on a more healthy appearance, while the ulcerated cavities gradually fill up without any accessory aid, and absorption goes on so rapidly that the leg day by day diminishes in size.

We have occasionally to deal with cases of a still more obstinate character, where the vapour douche comes in to

afford us some hopes of alleviating, in a marked manner, a disease which hitherto has baffled all our best resources. I allude to cases of Elephantiasis, such as we observe in these climates. It is, properly speaking, a skin disease, generally appearing in the lower extremities, but also attacking the face and hands; in this country we do not see it very often in any other form than that of swelled leg. In warmer climates the great relaxation of the skin goes on, *pari passu*, with its increasing hypertrophy, and large folds are formed, which often hang over the ankles and toes, so that the foot and leg form a large shapeless mass. In three cases which I have lately met, the foot and leg were swollen to a very great size, the calf of the leg measuring over twenty inches in circumference. Knowing the hopeless character of this affection, I was not very sanguine of any success by any line of treatment open to me, so I determined to persevere with the vapour douche, even though I could detain such patients in the hospital but for a short period. I had the satisfaction of seeing, at the end of a month, a decided change for the better in the appearance of the legs; in one of the cases, where there were fifteen small ulcers, the healing process had set in, and the leg was reduced by five inches in circumference—an effect which, I think, could not be procured by any other means.

I could scarcely have selected three more unpromising cases to show the benefits arising from the use of the vapour douche. In these cases I purposely abstained from all other local applications, as of ointments or medicines of any kind, while under the douche, giving all a good and generous diet under our invigorating atmosphere. I allow the fullest credit to these latter important adjuvants, but I think the rapid diminution in the hypertrophied state of the skin must force us to conclude that some more potent power was at work than heat, and moisture. Heat and moisture will, in many cases, promote a healthy state of diseased parts, but there is generally a limit to improvement; and we find a state of relaxation of the vessels and soft parts following the continued use of these two applications, and then some other stimulant besides heat becomes necessary to give tone and energy to complete the reparative process.

In referring to the first case, that of J. G., we must admit that the electrical state of the vapour constituted the stimulant which was directly necessary to secure a more vigorous circulation in the entire vascular system of the diseased part; and, as a consequence of this, not only the absorption of effete matter, but the deposition of more healthy materials to rebuild such a disorganized structure. It was also remarkable that I had no necessity for bandages or any medicated applications; the extensive sore went on progressively healing until perfect restoration took place. We know that a positive current of electricity will cause the circulation of fluids in capillary tubes, so, when it is united with heat and moisture, we have three great principles forming a powerful agent, which, from the results obtained in the few cases I have given, may yet be of important service in many formidable diseases that have hitherto resisted the most scientific treatment.

I am aware that I am going out of the beaten track in thus recommending this form of electricity combined with heat and moisture, and some may have strong doubts that such a combination of forces can be brought into action. No doubt we cannot utilise the power of electricity by depending upon any of the forms of apparatus for producing galvanic and magnetic electricity. In these latter we have to deal with the interrupted current which generally cannot be applied to delicate inflamed surfaces without giving pain; but when we can insulate the patient, we know we can make his frame the medium of a current of electricity, which becomes a continuous one, and which, when carried by the steam douche to any particular part of the body, can there expend its influence in the most beneficial manner.

In using the term steam, or vapour douche, I must not be understood to mean a jet of steam forced

through a simple tube, for in that case the steam itself, when pure, has nothing to do with the phenomenon of electricity; this latter is manifested only when water is at the same time present, and is altogether the effect of the friction of the globules of water against the sides of any substance opposed to its passage, as the water is rapidly moved on by the current of steam. Accordingly, the electricity is found to be increased in quantity by increasing the pressure and impelling force of the steam. Faraday found that the immediate effect of this friction was, in all cases, to render the steam or water positive, and the solids, of whatever nature they might be, negative. My object, then, was to utilize this current of electricity, so that it should pass with heat and moisture to any part of the body requiring it, and, by insulating the patient, and, if possible, the boiler, or generator of the steam, take advantage of the combined effects of this powerful continuous current, so beautifully exemplified by the hydro-electric machine, invented in 1845, by Mr. Henry Watson, of Newcastle, and the present Sir Wm. Armstrong. This machine was first exhibited at the Polytechnic, where it was the wonder of the day, as showing the enormous quantity of electricity that could be produced by effluent steam under high pressure; but, strange to say, notwithstanding the eager search after novelties at this present day, this wonderful machine has been consigned almost to oblivion. I am not aware that steam under high pressure has ever been used as the means of applying electricity in a medical point of view to such cases as I have mentioned, with such remarkably beneficial effects.

If I am sanguine that great good must follow its use, I am so on the foundation of actual experiment; and in opening this new field of observation to the profession, I see no reason why others should not obtain the same good results, and thus give stronger proof that we are at last on the straight path for utilizing this powerful agent to the great benefit of suffering humanity.

To Mr. Henry Watson, of Newcastle, I am very much indebted for his readiness in affording me every information on the construction of his hydro-electric machine, and for his kindness in placing it at my disposal.

It would, indeed, be most desirable that such a powerful agent as the high-pressure steam douche could be brought within the reach of the profession at large. Most of our hospitals find it necessary to have a high-pressure steam boiler to work an engine as a general power, working at a pressure of about 90 lbs.; to such boilers there could be no difficulty in applying the condensing box and jets, as originally constructed under Mr. Watson's directions; and although the boiler would not be strictly insulated, yet with a pressure of 50 to 60 lbs. we should get such an amount of electricity as in the generality of cases would be required.

I feel confident we have much to learn from the proper use of this steam douche, and I shall feel gratified if, by this short notice, I shall stimulate others to work in this new and extensive field of inquiry.

NOTES ON VEGETABLE PARASITIC DISEASES OF THE SKIN.

By HENRY SAMUEL PURDON, M.D.,

Physician to the Hospital for Diseases of the Skin, Belfast.

FUNGI are to be observed on old books, ink, cheese, &c., especially when placed in damp localities, as well as in many forms of cutaneous diseases. The presence of damp seems to excite their growth: one particular disease, favus, is common here, and in other countries similarly circumstanced, as, for instance, Holland. It is rare in dry localities. It may not be generally known that Ireland has been, within historic times, at least, similarly situated to what it is at present. Dr. Knox,* after referring to the

writings of the Venerable Bede and the annals of the Four Masters to show the close connection between the climate of those days and that of the present, then proceeds to sum up its prevailing characteristics as follows:—"The distinctive marks of the Irish climate may be enumerated as the general prevalence of westerly winds, of sharp easterly gales in spring; the mildness of its winters and comparative coldness of its summers; its dampness at all seasons; and general equality of temperature." Here in Belfast, the capital of Ulster, well known for its moist climate, I have had fourteen cases of favus out of 3,000 skin diseases of all kinds. During my student days in Dublin, I frequently saw this disease amongst the out-patients at the hospitals. Again, in Glasgow I know from personal observation that favus is rather common. On the other hand, in London, a much drier locality, favus is a rare disease.

From the result of observation it is now known that the rainiest regions of Europe are Norway, Ireland, and west coast of Britain. The Rev. E. McClure, M.A., has been kind enough to calculate for me the average rainfall during the last five years in the following places—London, Glasgow, and Belfast, which is the only means available for arriving at the moisture and dampness of climate. I may, however, state that further particulars will be found in "Tables of the Total Depth of Rain," compiled by J. Symons, M.B.*

AVERAGE RAINFALL FOR FIVE YEARS, 1864-68.

London	23·7 inches.
Glasgow	43 07 "
Belfast	34·70 "

The frequency of favus and tinea circinata will be observed in the following table:—

London	{ Favus 1 in 2000...Mr. Wilson, <i>Jour. of Cut. Med.</i> No. 3
	{ T. circinata & T. tonsurans 60 ,, 2000... Do. Do.
"	{ Favus 1 ,, 1000...Mr. Milton, "Modern Treatment of Skin Diseases."
	{ T. circinata & T. tonsurans 19 ,, 1000... Do. Do.
Glasgow	{ Favus 118 ,, 6451...Dr. McCall Anderson, "Report of Dispensary, 1867."
	{ T. circinata & T. tonsurans 91 ,, 6451... Do. Do.
Belfast	{ Favus 14 ,, 3000...Dr. H. S. Purdon, "Report of Dispensary, 1863."
	{ T. circinata & T. tonsurans 47 ,, 3000... Do. Do.

The growth and development of fungi are favoured then by moisture, warmth, and a copious supply of "nitrogenous with some hydro-carbonaceous nutriment." Indeed, Küchenmeister† has informed us that fungi prosper the richer the soil is in organic nitrogenous substances; and the late Dr. Golding Bird‡ stated that whenever the functions of the skin are impaired, "where a due amount of secretion is not exhaled from the surface, an excess of nitrogen is retained in the blood. That nitrogenised products are exhaled from the skin is indubitable."

The reason that I have selected favus is that it is a more matured form of growth than either tinea circinata or tonsurans; indeed, the modern view is that we have only one parasite, which, differing in different constitutions and localities, gives rise to various lesions.

Many forms of parasitic diseases are observed in the vegetable kingdom: the common forms of blight, smut, and mildew, known to every farmer, are examples, and no doubt have their counterparts in many of the cutaneous diseases incident to man. Internal organs and structures may also be attacked: for instance, *sarcina ventriculi*, giving rise to dyspepsia; the *oidium albicans*, causing the disease known as "thrush." That most formidable malady, cholera, is asserted to be due to the introduction into the system of a fungus by some considered to be the *cladoporium herbarium*, a small superficial fungus occasionally found on rice, especially in warm countries.

With regard to the *dermatophyte*, Hallier thinks that

* London: G. Shields, Great Sloane street.
 † Animal and Vegetable Parasites, Sydenham Society, vol. ii. j
 ‡ "On Urinary Deposits," page 136.

* "On Irish Watering Places," page 319.

the *penicillium* is the cause of tinea tonsurans, tinea circinata, and sycosis. Pick,* a former assistant to Hebra, has succeeded in transplanting this fungus upon the human skin, when sometimes favus and sometimes tinea tonsurans were developed, and whose experiments tend towards proving the identity of the fungus in favus, tinea tonsurans, and sycosis; indeed, the doctrine of polymorphism is pretty generally accepted by dermatologists in the present day. In alopecia acuta the parasite is not easily detected at all times. This disease is very rare in Belfast, as during the last four years I have only met with some five or six cases out of about 4,000 skin diseases; on the other hand, when in London, last March, I saw in one day six cases occurring amongst the out-patients at the Hospital for Skin Diseases, Blackfriars, and Mr. Sims informed me that it was rather common. The parasite, the *microsporon andouini* has only a feeble hold of the epidemics, and the changes in the structure of the affected hair are due, according to Dr. Reid † to the presence of the parasite at the hair-bulb, interrupting its nutrition and exciting a certain amount of irritation; the fungus, moreover, diffuses itself among the epithelial scales; producing a certain amount of thickening and enlargement of the sheath. Dr. Tilbury Fox ‡ holds that fungi will not flourish on a healthy surface, "but grow upon those that are most prone to non-specific eruptions, and for this reason vegetable parasitic diseases occur in young life, diminishing rapidly in frequency as adolescence advances, the least expressed form, tinea deculvans (alopecia acuta), being most common in adult life."

In concluding these "rough notes" it may not be out of place to venture one or two remarks on parasitocides, and, by way of preface, the following observation of Küchenmeister is here recorded, viz., "Acetate of copper and other strong local remedies irritate the skin too much and accelerate the growth of the fungus enormously." The only exception to which the above rule does not apply is in the case of blisters. Parasitocides may be divided into those derived from the vegetable, animal, and mineral kingdoms; but, without going deeply into the subject, it may be briefly stated that the most valuable obtained from the first are iodine, creosote, carbolic acid, and acetic acid. The last three check the development of spores; creosote, according to M. Béchamp, although it allows the mycelium to form, prevents the spores from germinating. I have recently tried a colourless tincture of iodine containing carbolic acid, made by Mr. Evans, State Apothecary, Dublin, and think that if made stronger it will prove a valuable application in time. Paraffine, turpentine, oil of cade, &c., are of inferior value to the above. From the second the only remedy of use is cantharides, which, when used in the form of the liniment of the British Pharmacopœia, quickly cuts short the disease, especially tinea tonsurans, circinata, and alopecia acuta; it likewise stimulates the affected skin to take on a more healthy action. From the mineral kingdom we have mercury, especially the bichloride, chromate, nitrate, and white precipitate, sulphur, borax, &c. The first has a well-earned reputation, and the chromate of mercury I am at present trying in tinea vesicolor, and some other forms of vegetable parasitic diseases; an objection to its use is that it does not mix with water, indeed, it is insoluble in any fluid, but may be used as an ointment. I have added glycerine and rectified spirit, so as to endeavour to suspend it in solution, but without success. The only way to manage is to shake the bottle before applying it. A useful auxiliary to the above remedies is in epilation, which should be performed in inveterate cases. Of course, constitutional treatment is of the utmost importance, quinine being our chief remedy; which substance, it is asserted, has the property of destroying vegetable growths. Dr. Binz§

has found that a neutral solution of chlorohydrate of quinine, soluble in sixty times its volume of water, has the power of destroying infusoria and fungi developed in vegetable infusions, and believes it has a peculiar antiseptic action different from other vegetable alkaloids. The tincture is the best preparation for children.

No doubt, the growth and development of a fungus is favoured by some peculiar condition of the system; for example, tinea vesicolor flourishes and is common on the bodies of consumptive patients. In two cases (with the assistance of Mr. Law, now Professor of Veterinary Anatomy, Cornell University, U.S.), I succeeded after several failures, in causing the fungus taken from an apple, on which the *achorion* had been transplanted, to grow on the inside of a rabbit's ear, which we had previously inoculated with tubercle. And in all cases of vegetable parasitic diseases coming under my care, I prescribe constitutional, as well as local treatment. Cod-liver oil, pancreatine, the syrup of the iodide of iron, quinine, and in hospital practice salicine, being the remedies relied on. Mr. Jabez Hogg's* views confirm the therapeutical fact that parasitical affections are rarely, if ever, "cured" by destroying the parasite, but they can be eradicated by administering appropriate tonics and alteratives which are capable of correcting the blood dyscrasia, which tends to keep up the disease.

THE POPULATION QUESTION.

By EWING WHITTLE, M.D., M.R.I.A.,

Lecturer on Medical Jurisprudence to the Liverpool Royal Infirmary School of Medicine.

IN his last communication Dr. Drysdale makes an attempt at answering the queries that I put forward in my recent letters on this subject, and I feel called upon now to point out wherein his arguments fail to make out his case.

1st. He refers his opponents to the article on "Population" in the *Encyclopædia Britannica*. I have taken the trouble to read this article, as reprinted in the edition for 1858, and what do I find? The whole argument embodied in a foot-note in these words: "No one will doubt the writer's fundamental principle that the amount of the human race must be in proportion to the amount of food procurable for their support." This is the famous law of Malthus; this is, as it were, their gospel; but neither Malthus nor any of his followers have ever attempted to prove its truth. On the other hand, we regard this as a mere assumption, and a false one, too. Doubleday has shown that there is a relation between the quality and quantity of food and population, but that this relation is very different from a mere ratio, quantity for quantity.

2ndly. As to France. Dr. Drysdale entirely omits the effect, as a check on population in that Empire, of the maintaining a vast standing army, and in that way enforcing a life of celibacy on half a million of the most vigorous men in the country, during the most energetic period of their lives; and as to the small families of the French peasants, Doubleday has shown that that is occasioned by the greater degree of comfort in which they live, than do their countrymen in crowded manufacturing towns.

3rdly. As to America. The Malthusians, in reckoning the increase of population, make a guess at the increase from emigration, and deduct that amount from the gross increase; but they do not make allowance for the increase by procreation among the emigrants themselves. But, even admitting the doubling by natural increase in twenty-five years in America, how can such conditions have any analogy with the conditions of an old settled country? In America, we have a new world thrown open to the industry of mankind; a young and vigorous people settled

* *British Medical Journal*.

on it; many inducements to early marriages; abundance of fertile land, but requiring labour to make it productive.

Here are all the conditions necessary for raising a vigorous and even rapidly increasing population, not inconsistent with Doubleday's views, and only apparently giving weight to those of Malthus. Contrast with this American increase of a doubling every twenty-five years, the increase of the mutineers on Pitcairn's Island, who, located on this inhospitable rock, and with difficulty able to get food from day to day, yet increased nearly ten-fold in forty years. What I have here replied to contains the whole force of the Malthusian assumption—argument it scarcely deserves to be called.

Now, what are the results of recent experience in this country? In Ireland we find that the rapid ratio of increase in the population of that country has been very considerably checked since the potato ceased to be the exclusive diet of the Irish peasant; and in England, as greater numbers of the masses, under the pressure of bad times and the operation of the new Poor Law, are forced to exist on poorer food, and often a scanty supply of it, so do their increasing numbers see the up around us, threatening, as they wax stronger in political power, to engulf society in one common ruin. If the theory of Doubleday be the true one, the remedies are obvious: the sweeping away of monopolies; the remodelling of taxation, so that it shall press as lightly as possible on the industrious masses; the return to true principles in the administration of the Poor Law, so as to raise the wages of the agricultural labourer sixty or seventy per cent. at least, even at the cost of involving a large reduction of rents. If these remedies were freely applied, we should soon find a check given to the rapid increase of the pauperised masses.

It would be unprofitable to pursue the argument further; the profession have now the evidence on both sides before them, and I have no doubt that they will, with few exceptions, hold by the views of Doubleday, as being more philosophical and reasonable than those of Malthus and his deluded disciples.

Liverpool: July 13, 1869.

P.S.—I have just received this week's number of the *MEDICAL PRESS AND CIRCULAR*, containing Dr. Murphy's letter. I am glad to see that the subject is attracting the attention of thoughtful members of the profession. If Dr. Murphy will read Doubleday's work, and compare his careful reasoning and his striking illustrations with the loose dicta of Malthus and the other political economists, I am sure he will be quite satisfied that the pretended law of Malthus is simply an error, but an error which, having been adopted as a dogma by a powerful school of politicians, has worked a vast amount of mischief.

Mr. Levy's letter (*MEDICAL PRESS AND CIRCULAR*, July 21st), calls for one or two remarks; any argument that it contains is more than answered by the paper to which this postscript is attached. He says that Doubleday "mistook cause for effect;" but the fact is, the Malthusians mistake effect for cause. Let all advocates of progress, however, take note of the fact that Mr. Levy, as mouthpiece of the Dialecticians, announces, on their behalf, that they abhor as *communists* the opponents of monopolies.

July 22, 1869.

MENSTRUATION IN DIFFERENT RACES.

AN examination of 100 Hebrew women, of 200 Slavonic peasant women, of 70 noblewomen in a very circumscribed district, gives the following results:—The peasant women menstruate at 15 years, 10 months, 9 days; the Jewish at 14 years, 3 months, 25 days; the women of nobility at 13 years, 1 month, 5 days. The Jewish and peasant women live under almost the same conditions, the former even being worse off in that respect. The double influence of wealth in the daughters of noblemen, and of the characteristic fecundity and the particular precocity of the Semitic race, can be easily deduced from statistics.—*Am. Jour. of Obstetrics.*

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

WESTMORELAND LOCK HOSPITAL.

HEREDITARY SYPHILIS.

By Mr. MORGAN, F.R.C.S.I., Surgeon to the Hospital, &c.

Hereditary syphilitic periostitis of the tibia, in a child two months old.

R. B., aged twenty-six, the mother of this child, has been twice the subject of genital sores; for the first time eight years ago, when she had a suppurating bubo; and again five years ago, when she had several elevated sores (probably condylomatous).

From that period she has never had any constitutional symptoms whatever; no pains, rash, sore throat, &c.; but is in good robust health.

Six years ago she had a dead-born premature child. She now has another at the breast, which is two months old; the sixth week it showed signs of disease, having a very extensive rash over the body, snuffles, and a few mucous patches. Chlorate of potash, in three-grain doses three times a day, was regularly administered.

A few days after admission the tibia showed evident signs of periostitis, being tender, and swollen nearly to twice the size of the other limb, and suppuration seemed imminent. By the use of fomentations and poulticing, this gradually yielded, but is not yet completely dissipated. The general health is much improved, and the child gaining condition.

Though periosteal affections in infants have been occasionally recorded, they are curious and rare; and the occurrence of so severe an attack in so young a child is a remarkable practical fact. The total absence of all symptoms in the mother for five years, and up to the present, shows the enduring latency of the disease, though it is, of course, an open question as to the father having been syphilitic.

SYPHILITIC AFFECTIONS OF THE LIVER IN THE FŒTUS.

Miliary syphiloma.

This term has been aptly applied by Gubler to that remarkable pathological appearance which occasionally occurs in intense hereditary infection, where the liver appears studded over with grains like semola, and the syphilitic deposit occurs in a very minute form.

A well-marked example of this hepatic deposit has been under my observation. The subject of it was a premature eight months' child, and had been dead for some days before delivery; the body was tolerably nourished, and there were no external evidences of any disease; the placenta was rather large, but not affected by fatty degeneration. I made a careful *post-mortem* examination, and found no change in the general viscera, excepting the liver, which presented the curious appearance of being studded over with a fine deposit both on the surface of and disseminated through its substance; there was an average of one deposit for about every square line on the surface, giving a remarkably speckled appearance to the organ, each being about the size of a small pin's head. The mother (B. R., Ward 6) at the time of delivery was suffering from extensive mucous patches.

As remarked by Lancereaux, it appears allowable to suppose that this difference between miliary syphiloma and the more marked but later deposit of gummatous matter in the liver is probably nothing else than the effect of a greater acuteness in the course of the disease, the termination of which is almost necessarily fatal.

Gumma on the liver in an infant five weeks old.

In contrast with the foregoing case of miliary syphiloma is the following, illustrating a gummatous deposit.

M. W. (Ward 6) was admitted to hospital with a female child at the breast, five weeks old. It was a picture of infantile syphilis, but had no patches about the mouth, nor had the mother any sore on the breast.

I treated it by the chlorate of potash plan in two-grain doses three times a day.

For the first few days the child seemed to improve, but gradually became emaciated, yellowish, and faded looking, and had diarrhœa. The abdomen was swollen, but there was no enlargement of the liver perceptible; notwithstanding every care, the child gradually sank.

On *post-mortem* examination, all the organs appeared healthy, but on the convex surface of the left lobe there was an elevated gumma, about the size of a large nut; it was dense to the feel, and gave the sensation of being a distinct deposit in the liver, shading off gradually into the hepatic substance, and this was the only deposit to be found in the organ.

The mother, aged twenty-four, is apparently perfectly free from all taint, and states positively that she never had any disease till she was pregnant about five months of this child, when she got a primary on the genitals, not followed by eruption or other signs.

Cases illustrating the communicability of non-primary syphilis.

The transmission of the venereal poison from a non-primary lesion, and its manifestation by the appearance of well-marked constitutional signs, is a curious and interesting question in the etiology of this disease. Its transmission by inoculation of the blood derived from a patient suffering from early secondary constitutional symptoms, as in the experiment of Dr. Bargioni, admits of little doubt; by the fœtus in utero, by suckling, by contact, by kissing, &c., the poison has been introduced into the system of the recipient, developing itself in various forms. As I have had under observation the father, mother, child, and grandmother, all affected from the same source, they present confirmatory evidence of the communicability of secondary lesions.

NO. 1.—THE GRANDMOTHER.

E. B. (Ward 5), a respectable married woman, was admitted June 24, 1869, suffering from well-marked and severe iritis of the right, and slightly of the left eye, a mucous patch at the angle of the mouth, and extensive mucous patches over the palate and fauces, pains in the bones, and a papular syphilide. Her age being sixty-eight, placed her beyond suspicion, and she had always been strong and healthy. About six months since she got a sore at the angle of her mouth, from her grandchild, who had sores at each angle, which were healing when the grandmother became affected, the child at this time had also some eruption of papules on the skin. The grandmother took care of the child, washed and fondled it, and dates the formation of the sore mouth as the starting point of her affection.

NO. 2.—THE GRANDCHILD.

The grandchild, a girl, aged nearly two years, was admitted the same day, suffering from a well-marked ulcerated patch at the anus, clusters of fine papules on the body, the mark of a recently healed gumma on the side, but the mouth perfectly healed, the child being otherwise the picture of health. She had been in last November under my care for mucous patches at the vulva, some isolated papules over the body, and a mucous patch at the angle of the mouth, which had existed some months, and had caused the formation of a sore on the right breast of the mother, near the nipple, the cicatrix of which is still apparent, although she herself was suffering from constitu-

tional manifestations, and had nursed no child but her own.

The child was then treated non-mercurially, and discharged apparently cured, but shortly afterwards the latent taint developed itself in such a form as to be capable of contagion.

NO. 3.—THE MOTHER.

The mother, a robust young woman, married three and a-half years, was admitted November 2, 1868, with her child, above referred to. She was pregnant, and suffering from severe mucous patches of the vulva, and a papular eruption, alopecia, and pains. During the first year of her marriage she became pregnant, and the child was cranio-tomized. She was free from any signs of taint, and remained so while pregnant of this child, and it was not till it was about nine months old that she observed its having any signs, or the sore mouth, but previous to the sore on the breast, she says she got the genital patches for which she is now admitted. She returned home, though not cured, much improved, and has since been delivered of a premature dead-born child. She is now (July, 1869) suffering from mucous patches at the genitals, and pains.

NO. 4.—THE FATHER.

The father, a hard-working mechanic, admits that about two years before his marriage he had a primary sore, but never since, and he is suffering at present from marked papular eruption and pains.

This family history demonstrates some interesting points in the course of the disease. Thus, after four years, the father produces a syphilitic child, which is an active source of contagion. The mother shows the intensifying nature of the poison by her carrying a first child to its full time, and remaining herself healthy. Her then producing a child which, after some months, shows unmistakable evidences of inherited poison, and is capable of transmitting constitutional syphilis to the grandmother. Her producing a third child, but premature, and dead-born.

The child proves the compatibility of constitutional inherited syphilis with the most robust, healthy, and well-nourished condition of body; the comparatively late development of the signs; the co-existence of contagious early constitutional signs with gummata as late developments; the possibility (according to the mother's account, and warranted by the cicatrix of the sore, still apparent on the breast) of the *child recommunicating a sore* to its own mother.

The grandmother proves the capability of the special form of mucous buccal patch transmitting the full influence of the poison.

In order to test if a primary sore could be produced by the inoculation of this secondary discharge, on the 16th of July I performed auto-inoculation on the person of the child. The discharge from the patch at the anus was inoculated in the side, and produced a pustule, followed by a sore. The matter from this pustule was inoculated in the other side on the 20th of July, and in like manner produced a pustule which is evidently specific.

WORKHOUSE HOSPITAL, GALWAY.

CASE OF CHOREA FROM MEMBRANOUS INFLAMMATION OF INTESTINE.

(Under the care of Dr. CLELAND.)

THE patient, Michael Ryan, æt. eleven years, was admitted on the 18th October, 1867.

He kept up a monotonous moan, repeating the exclamation, "Oh! oh!" continually, from 8 o'clock in the morning till the same hour at night, when he ceased; and about 10 o'clock he would go to sleep, and continue

quiet until the following morning. He complained of constant violent pain in a spot at the back of the head, and of uneasiness in the stomach. He was rather thin, his colour bad, his eyes had a heavy expression, and he picked his nose. He answered intelligently, and by keeping up a constant series of questions, the moaning could be prevented for a minute or two, but it instantly recurred when the slightest pause in replying was allowed.

He was said to have been affected in this way for three weeks. It was subsequently ascertained from his father, that the boy had been quite healthy till 3rd June, 1866, when he complained of pain in different parts of his head, and began to fling himself about, jerking and tossing his limbs irregularly. He had continued ill for three months, during the latter two of which he complained of difficulty in swallowing; he then got suddenly well, and remained so until three weeks before his admission.

October 19th.—Administered cusso and scammony; no worms came away. A certain amount of retching occurred, interrupting the moaning.

20th.—A blister, 4in. by 4in., placed on the back of the neck; and two grains of blue pill ordered to be given twice a day.

21st.—There being no improvement, five-grain doses of quinine were directed to be given three or four times during the night, in the hope that the attacks, being of quotidian periodicity, might be thus checked.

23rd.—The moaning was louder, continuing as before for twelve hours, broken every second minute or so with violent retching, which, however, involved only the pharynx and larynx,—at least, the patient frequently stopped moaning and retching to drink, and did not throw off what he drank. The noise and exertion were so great that it was deemed expedient to try to put the boy to sleep. Twenty-five drops of laudanum were administered at 11 a.m., and followed half an hour after by fifteen more, without effect. Within half an hour after the second dose he was put under the influence of chloroform, and when the deep breathing produced by the anæsthetic passed off, he continued to sleep soundly for about an hour, when he began to start and struggle with the attendants, throwing his limbs violently about, but without recurrence of the moaning or retching; his eyes continuing closed and the eyeballs so much turned up that the pupils could not be brought into view. Thus he remained till 4.30 p.m., when he awoke, and began moaning and retching as before.

24th.—Reverting to the belief that intestinal irritation might be the cause of the illness, Dr. Cleland ordered an infusion of two drachms of cusso, to be followed in the evening by castor oil and turpentine.

25th.—According to the wardsmen no worms had been passed, the patient, however, was perfectly quiet this day. He still complained of pain in the head. The cusso and purge were repeated, and directions given to the wardsmen to look for membranes in the evacuations.

26th.—The stools passed after the medicine the night before contained great numbers of thin shreds, which were washed by the wardsmen, and kept for inspection. They were very thin, not opaque, nor white. Under the microscope they were seen to be shreds of false membrane full of granules, and with large granular corpuscles still unbroken here and there.

29th.—The patient was yesterday ordered cod-liver oil. The pain in the head was not gone, but seemed to be better.

November 10th.—During the day before yesterday he coughed a good deal, the cough being evidently in considerable part nervous. There was some recurrence of moaning, which in the evening became monotonous. Yesterday, the moaning began at eight o'clock in the morning, and continued till eight at night, as formerly, only instead of being broken with fits of retching, it was interrupted with fits of coughing. The castor oil with turpentine was again exhibited, and to-day he is quite

quiet, but still coughs a good deal. Ordered six grey powders of eight grains each, one to be taken daily.

17th.—The cough continued all the week, and for the last few days has recurred about every second minute during the visit of the doctor. The patient was expostulated with, as the cough evidently depended little on any bronchial or laryngeal irritation, but might be checked by exercise of the will, and a threat of removal from the ward appears to have had the effect of stopping it altogether.

January, 1868.—Some weeks after the preceding notes were taken, the lad continuing to improve in general appearance, and being able to sit up, it was found that he was losing the power of walking. On examination, it was discovered that though he could move his limbs, he was unable to stand, or make any approach to walking farther than staggering forwards when well supported. He remained till the beginning of this month with little improvement in this respect, and still complaining slightly of pain in the head, when his friends took him home.

January, 1869.—From inquiries made afterwards it was found that the patient soon recovered his health without further treatment, and is now stated to be perfectly well.

SCOTLAND.

LADY DOCTORS.

THE ladies have triumphed. We are enabled to announce that the Edinburgh University Court has sanctioned the admission of ladies to medical study. Miss Gex Blake and others will at once matriculate. The Court, we are informed, in this matter, acted on the advice of the Senatus Academicus and of the Faculty of Medicine. It is necessary for the measure to be submitted to the General Council of the University, at the next half yearly meeting, when, if approved, it must be ratified by the Chancellor. It is not likely that the latter would veto it, and it is not expected by the advocates of admitting ladies, that the medical element in the General Council will be desirous to prevent a trial of the plan, inasmuch as it is expressly stipulated that the ladies are to study in separate classes from their brother medical students. Should these new classes succeed, it will not be surprising to find other institutions following the example of the University of Edinburgh.

THE VACANT CHAIRS.

VARIOUS speculations are afloat as to the vacant Chairs, in regard to which the medical public seem to require some enlightenment. First as to the Chair of Clinical Surgery, Mr. Syme is not understood to have definitely resigned, though believed to be, nor unwilling to do so on certain conditions. He is now remarkably well, and is quite entitled by his past services and present state of health to follow the course that seems to him best.

As to the would-be candidates, Mr. Lister's claims have been too much based on his carbolic acid theory, which will no doubt prove just such another gigantic bubble as the great sulphur cure, leaving, however, on bursting, some permanent good. A modest and retiring man of science, Mr. Lister has never made much way with the profession in Glasgow, and it is doubtful if he is quite the man to succeed his distinguished father-in-law, whom he could certainly never hope to equal.

Mr. Spence is a practical surgeon of great and distin-

guished ability, but not one whom the profession would willingly see elevated to the Clinical Chair after his very un-called for and misplaced advocacy of the present site of the infirmary—an advocacy which every right-minded man must be glad to know has proved fruitless.

Dr. Joseph Bell only wants a few more years to render him [a] most eligible candidate for any Surgical Chair; at present seniority gives others the preference.

Of these senior none possess higher claims than Dr. Patrick Heron Watson, whether we regard his manual and mechanical dexterity, his great powers of diagnosing, his large experience, or his friendliness of disposition, all of which make him a great favourite both with the public and the profession. But, unfortunately, Dr. Watson has hitherto been a general practitioner, and the same bar which proved formerly insuperable to Mr. Miller and Dr. James Duncan, cannot but form a strong objection to him. Moreover, the profession has not yet been thoroughly enlightened as to his relation to homœopathy in regard to the late Lord Belhaven; and neither general practice nor the coquetting with homœopathy can be tolerated in the occupant of the Chair of Clinical Surgery, the successor of our great, and in every respect, pure Mr. Syme.

For the Chair of Pathology there are only three candidates, and these so unequal in merit that to those who know them it must seem quite superfluous to state their differences. The most recent of these candidates is Dr. Smart, author of very interesting reports on the pathology of the cattle plague, but who, though an able student, is yet wholly unknown in connection with human pathology. Quite recently a cattle pathologist was required for the veterinary school, and the successful candidate's claims were based chiefly on a testimonial from Mr. Ward Hunt. Dr. Smart would have proved a most able cattle pathologist; we doubt whether even a testimonial from Mr. Ward Hunt would suffice to glide him into the Chair of Human Pathology.

The second of these candidates in order of distinction, the first in order of time, is Dr. Grainger Stewart, the present pathologist in the infirmary. This, it must be remembered, is an office with a great name signifying little, its occupant is simply the man whose duty it is to open the bodies for physicians who have the right of exhibiting the parts and prelecting on their pathology; it is an office sought after, by young medical men, previous to their entering on the higher duties of physicians to the infirmary. Dr. Stewart has discharged his duties with considerable ability; how great and how acceptable his services have been will be of course best judged by the testimonials of his coadjutors in the hospital, who have very kindly allowed him to further his fame by publishing their cases. Oblivious of our censure of unprofessional advertising, Dr. Stewart has not hesitated for weeks past to advertise daily his work on "Bright's Disease," and this circumstance alone ought to stamp the man in the eyes of all right-thinking medical men as more of a seeker after self than after science. Far otherwise is it with his most distinguished opponent Dr. Sanders, who is the senior physician in the infirmary; and whose claims, though well known to the profession, are too little known to the public who have so great an influence in the elections to all Chairs, the patronage of which belongs to the curators. Dr. Sanders' claims to the Chair are based on pathological works of the very best kind, extending over more than twenty years. His work "on the Structure of the Spleen" will of

itself suffice to transmit his name to posterity, while his researches on amyloid degeneration were amongst the very earliest investigations of this singular affection, and have been confirmed and adopted by all subsequent pathologists. His more recent investigations into the pathology of aphasia and other peculiar forms of paralysis have shown Dr. Sanders to possess mental powers of the very highest order in regard to the elucidation and explanation of the pathological nature of a class of diseases which are involved in the utmost obscurity, and which from their importance must always retain a very high interest for the profession. Modest and retiring to a degree inconsistent with that push so needful now-a-days to advance a man in these days of great competition, it is quite necessary that all who respect scientific attainments, and who consider them the best guarantee of future usefulness in such a distinguished position as the Chair of Pathology in the University of Edinburgh, should use their utmost endeavours to promote the success of Dr. Sanders; and the more close and intimate the enquiries made into the attainments and work of all the candidates, the more certain we are that the enquirers will concur in the recommendation we have given.

OPERATION FOR IMPERMEABLE STRICTURE OF THE URETHRA.

G. M. BURKE, Sulphur Springs, Ind. (*The Western Journal of Medicine*), publishes the following interesting operation for impermeable stricture of the urethra in a male aged thirty-six years: When called to the case, January 11th, 1869, he was found suffering extreme pain from retention of urine, caused by stricture of the urethra. The extract of belladonna was applied to the penis and perinæum, and the patient was placed in a tub of hot water, all covered with a quilt, with the exception of the head; four grains of powdered opium were administered. Before taking him from the bath, a small catheter was introduced down to the stricture, and on withdrawing the catheter, it was followed by urine in a small stream about the size of a small knitting-needle; with great straining, his bladder was partly emptied. During the next four or five days remedies were constantly ordered to quiet him; but on the 16th of January he made up his mind to be operated on, and was prepared as for lithotomy, on the operating table. The incision was commenced immediately over the end of the staff, which had been previously introduced into the urethra until it came in contact with the stricture, which was an inch and one-fourth from the meatus urinarius; the mesial line was the guide, and the urethra was laid open an inch and a half, but he failed in passing the instrument beyond the incision; another incision was made, splitting the septum scroti to the depth of three inches, and laid open the urethra, but failed to advance the staff; next incision was made from the urethra downwards, backwards, and outwards, until the sound and sensation to the operator changed to that of cutting a green pear or sole-leather, which did not cease until the urethra was laid open through its membranous portion; the change in the cutting and appearance of the urethra gave evidence of the stricture being divided, and with some difficulty a No. 8 catheter was introduced into the bladder, and urine escaped by the catheter and around it to the amount of a quart.

Patient recovered from the influence of chloroform without any untoward symptoms; he was placed in bed on his right side; catheter secured by a T-bandage; a large dose of morphine was administered; sides of wound brought in apposition, with cold mucilage of elm bark applied. Little blood was lost during the operation.

He was discharged from constant attention on February 5th, with instructions to introduce the instrument every day, allowing it to remain for two or three hours.

He is now walking about, able for business, and can pass his urine without pain or difficulty, in a stream near the size of No. 8 catheter; no indications of the size of urethra diminishing; suffering no pain or uneasiness of the parts, or along the course of urethra; continues use of No. 8 instrument every day; he is enjoying good health, and has a fair prospect to live to a good old age.

THE MEDICAL COUNCIL AND THE BIRMINGHAM MEMORIAL.

It is thought by many that the profession will shortly be asked to decently inter the body which has done nothing but squander in useless talk, extending over eleven sessions, the money it has extracted from the practitioners about whose fate it is so indifferent, and to whose complaints it turns a deaf ear. The Council has evinced a fixed determination to do nothing, an obstinate resistance to all improvement, a blind defiance of professional opinion. It is impossible to conceal the fact that, while the profession has lost all confidence in the Council, that cumbersome body never has had any real confidence in the profession. The vested interests of obsolete corporations are defended by councillors who are paid for another purpose by those who would gladly put an end to these conflicting claims. The Council declares it necessary to obtain an amendment of the Medical Act, but has just done the utmost to prevent any such consummation. What Government can be expected to pay any attention to the statements of a body in whom no one has the least confidence, and which refuses to consider whether it cannot be so changed as truly to represent the great profession which is taxed to support it?

We are not speaking at random. The memorial presented by Dr. Bell Fletcher was stated to have been signed by 5,200 practitioners. The number who have now signed it is nearly 10,000—more than half the profession of the three Kingdoms. This surely was entitled to the utmost respect, but has been really treated with contempt. No one can peruse the report of the committee by which it was shelved without admitting that there is the greatest variance between the Council

and the profession. It is by no means necessary to deny that the memorial in question may have asked for more than the Council had power to give. We are not now defending the memorial, nor do we wish to give an absolute adherence to every one of its points; but we do maintain that the first duty of the Council was to see whether it could not do something to gain the approbation of the memorialists. To have refused to consider the representations of such an immense number of practitioners is enough to stamp the Council as utterly at variance with the profession, and as only fit for a radical reform.

We append a copy of the memorial, and would beg our readers to compare it with the report of the committee that shelved it in our last number:—

MEMORIAL.

The undersigned members of the medical profession respectfully submit to the General Council of Medical Education and Registration of the United Kingdom, the necessity of obtaining an Act of Parliament to amend the Medical Act of 1858, and the Acts subsequently passed with a view to amend it.

The Act of 1858 affirms that “it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners.” The experience of the past ten years has proved that the Act is practically inoperative as a guide to the public in distinguishing legally qualified members of the medical profession. A large number of men are practising medicine and surgery in different parts of the country, not only without any legal qualification, but without having undergone any regular course of medical education. In some places men are practising under fictitious names, assuming the title of doctor, and obtaining considerable sums of money from weak persons, by intimidation and extortion. The Medical Act of 1858 is practically inoperative in restraining these offenders.

It is capable of proof that some legally qualified men have lent their names to persons without qualification, to enable them to practise medicine and surgery without incurring liability to prosecution. Such a proceeding is regarded as a fraud on the public and the profession; and it is suggested that in any future Bill great powers be given to the General Medical Council to remove from the Register, and deprive of their professional rights, qualified men who shall aid and abet illegal practitioners.

The present state of the law touching certificates of death greatly favours the successful practice of secret poisoning and infanticide. It is suggested that the certificate of a legally qualified member of the medical profession, in the absence of a coroner's order, shall be indispensable as a preliminary to every burial.

The Medical Act of 1853 purports to constitute the General Medical Council for the purpose of regulating medical education and registration throughout the United Kingdom; but composed as the Council is, mainly of the members of the medical corporations who grant licences to practice, the control of the system of medical education has proved to be very imperfect.

The undersigned are of opinion that the system of medical education should be revised, so as to ensure the possession of a thoroughly scientific and practical acquaintance with medicine and surgery, on the part of persons applying for the legal qualification.

To this end it is held to be necessary to substitute for the present system of examination, and for the many forms of licence to practice now granted, one high and uniform standard of examination, and one legal qualification.

The practical part of the course of professional study stands in special need of improvement, and the undersigned would gladly see the regulations made stringent, to ensure the attendance of students on a thorough course of practical study in hospitals; but in the event of any student engaging in private practice on his own responsibility before he is legally qualified, it is suggested that he forfeit the year or years as a student during which he has so practised.

It is respectfully but very earnestly submitted, that the influence and power for good of the General Medical Council would be greatly extended with the profession and the public if provision were made in a new Act of Parliament for the representation on the Council of the general body of practitioners

of medicine and surgery, who are now for the most part deprived of any professional franchise.

In any future Act of Parliament it is suggested that provision be made for instituting prosecutions under it by a public prosecutor or other public functionary on behalf of the General Medical Council, instead of leaving the voluntary enforcement of the law to individuals.

The undersigned desire to obtain no privileges for the profession without giving the public commensurate advantages; and they submit that an Act of Parliament so framed as to raise the standard of professional efficiency to protect life, and prevent the obtaining of money on false pretences, is an Act as much needed in the general interest of the community as for the welfare and honour of the medical profession.

THE GARIOCH AND NORTHERN ASSOCIATIONS' APPEAL TO THE COUNCIL.

THAT the Medical Council is unworthy of confidence, and is determined to do nothing to put an end to the distrust of the profession, is further shown by the way in which the letter of Dr. Struthers, on behalf of the Garioch Association, was suffocated by a committee.

This letter touches only a smaller issue. It supports forcibly the mode of representation of the profession in the Council that we have long advocated. It is temperate, and well deserved the attention of all concerned. It was but an appeal for representation by those who are taxed, but was utterly ignored. Here is the letter in question:—

Inverurie, Aberdeenshire, May 1, 1869.

To the President and Members of the General Council of Medical Education and Registration of the United Kingdom.

Gentlemen,—At a meeting of the Garioch and Northern Medical Association, held here this day, the subject of the want of direct representation of the medical profession in the General Medical Council was considered by the Society, and it was resolved to communicate to you the opinion of the Society, that provision for such representation should be made in any amendment which may be proposed on the Medical Act.

The Association begs leave respectfully to submit the following statement and reasons in support of this opinion.

As the Council is now constituted, three-fourths of its members are elected by the Licensing Corporations, the remaining fourth being nominated by the Crown. The result of this constitution of the Council is that the interests of the licensing bodies are represented rather than those of the medical profession at large. The admitted evil of so many examining boards (nineteen in number) conferring diplomas by equally numerous and sometimes conflicting examinations is thereby perpetuated. Besides the inconveniences to the student, and the obstacles thus created to a better system of medical education, the standard of preliminary and professional examinations cannot be raised, as the competition among so many licensing bodies is naturally a competition downwards.

Moreover, the funds by which the expenses of the Medical Act, including those of the General Medical Council, are met, are provided not by the Licensing Corporations nor by Government, but by a direct tax on the members of the medical profession. Thus those are represented who are not taxed, while those who are taxed are not represented.

One of the methods by which it has been proposed to accomplish the object in question, is by adding to the Council members elected by the direct votes of registered practitioners, arranged in districts. In the event of this method being adopted, the members thus elected, together with those nominated by the Crown, should not be less in number than those elected by the Corporations.

The other method which has been proposed is that the representatives of the Corporations, instead of being elected as at present by the governing or admitting body, should be elected by the members or graduates; those for the Colleges by the fellows, members, or licentiates; those for the Universities by the graduates.

The latter would be at once the more simple and the more complete of the two methods. It would avoid increasing the number of the Council; it would require simply a declaration to the effect that all registered members, or graduates of the Corporation shall be entitled to vote in the election of its representative; and by it there would be secured the representation both of the profession at large and of what is good and of public interest in the Corporations.

The Association therefore respectfully expresses the hope that in any amendment of the Medical Act, clauses will be inserted by which the object in question,—the direct representation of the profession in the General Medical Council,—will be secured.

I have the honour to be,

Mr. President and Gentlemen,

Your obedient servant,

JOHN STRUTHERS,
Chairman.

AN INDIVIDUAL APPEAL TO THE COUNCIL.

AMONGST those who have paid most attention to medical politics generally, no one has shown a greater interest in the reform of the Medical Council than Dr. Prosser James. It is, therefore, not surprising that he, as an individual, should have addressed that body at the present crisis.

His letter, when read at the Council, was referred, as we have reported, to the same committee as the other documents, but was not inserted in the minutes, as it was only the appeal of an individual. This procedure is, perhaps, quite right, as no one could desire an indefinite increase in the already bulky minutes. Moreover, nothing was lost thereby, as the author furnished every councillor, as well as the reporters, with a printed copy.

The wrong of also shelving this appeal is, of course, on a par with the whole conduct of the Council, but perhaps it is a still greater evidence of the hopelessness of the case, inasmuch as the reform asked by Dr. Prosser James was easily attainable, without expense, without legislation, and without the exercise of any power beyond that of recommendation—to which the Council so loves to confine itself.

Had some such resolution as that proposed in the letter in question been adopted, it would have satisfied thousands; while it would have shown that the Council had some little respect for justice, and for the wishes of the profession. As it is, there remains nothing for reformers but to circulate the letter to show how small a reform the Council has refused to grant. We print the letter by way of doing our share in the task:—

TO THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.

18 Dover street, Piccadilly,
June 28th, 1869.

SIR,—I am desirous of laying before the Council over which you so ably preside some considerations as to its constitution, which are deserving, I conceive, of its immediate attention, and a suggestion for its amendment, which, if adopted, would, I believe, tend to place it in

greater harmony with the profession of which it is the natural head, and thus increase its influence and the confidence of the public in its counsels.

You are aware, Sir, of the interest I have for years attached to the questions involved, and the considerable sacrifices I have made to promote what I believe the interests of my profession. I trust, therefore, you will excuse the reference it seems needful to make to my own exertions in order to render plain the present position of affairs.

Before the Medical Council was actually formed, I had been mixed up in various attempts to obtain an Act to regulate our profession, and in 1857 was in correspondence with some of Her Majesty's Ministers, and other statesmen, as to the rival plans that had been proposed. I had the honour, towards the close of that year, to submit to the late Lord Palmerston a memorandum of a practical scheme of medical reform, embodying a part of that which eventually became law.

You will not have forgotten that Mr. Headlam brought in a Bill to form a Council, consisting of delegates from the various corporate bodies—an idea eagerly accepted by many, while Lord Elcho, on the contrary, proposed a Council composed of Crown nominees. The existing Council is a compromise between these two plans.

The idea of a Council was, at that date, very generally approved, and my concern was to make it truly representative of the profession over which it would exercise so great an influence. This, I urged, might easily be accomplished by vesting the choice of the members of the Council, not in the governing bodies of the corporations, but in those members of the profession who had been authorised by them to practise, and such, I have reason to believe, was the intention of the Government in framing the Act of 1858.

The fourth clause of that Act declares that—

“The General Council shall consist of one person chosen from time to time by each of the following bodies—that is to say :

“The Royal College of Physicians,

“The Royal College of Surgeons,

“&c., &c., &c.”

Now, the natural meaning of these words surely implies that all the persons composing these bodies should have a voice in *choosing* the members of the Council. I am aware that many members of the Legislature thus interpreted the clause, and I believe that it was intended to be so construed, and thus to give effect to the plan I had recommended.

What, however, has been the history of the measure? The governing committees of the corporations have, for the most part, assumed the right to nominate the member of the Council, and exercised it (as I am inclined to think, in many instances, *illegally*) by deputing one of themselves.

It would be no trifling matter for an individual to appeal, in such a case, to the Courts of Law, though I think it possible that such a course might, in some circumstances, become advisable; and I am convinced, that so strong is the feeling of the profession, that if, finding no other means of compassing the end, I entered upon such a struggle, it would be with the unanimous approval and support of my brethren. It is, however, probable that it would be an easier and less costly process to obtain an Interpretation Act. One thing would be much in favour of this—viz., that small self-elected bodies, independent of those who support them, are utterly at variance with our national institutions, and irreconcilable with the spirit of the age. Nothing but the extension of the franchise of the corporations can save them from the suspicion with which antiquated oligarchies are everywhere regarded.

The General Medical Council, as it now exists, is an oligarchy of lesser oligarchies—it is the corporation of the corporations—and cannot but perpetuate their defects. It no more represents the profession by which it is sup-

ported than did the corporations it was intended in this respect to supersede.

I do not forget, that besides the occupant of the presidential chair, who is elected by the whole Council, and has hitherto been wisely selected from beyond the corporation delegates, there are six nominees of the Crown, so that it may be said there is a certain check upon the representatives of so-called vested interests. Nor do I wish to object to any individual who has obtained a seat at the Council. Nor is it needful to inquire what has already been accomplished. Ready, even anxious, to give the utmost credit to every one, I must yet maintain the urgent need of improving the constitution of the Council, inasmuch as it does not represent the profession, and is consequently deprived of the confidence it ought to enjoy.

The various schemes that have been proposed for its amendment—some within the Council itself—abundantly testify to the dissatisfaction that exists, and which, I believe, may be removed by the extension of the franchise of the corporations in the manner already indicated. Once let the members of the Council be thus elected, and instead of a body analogous to Convocation, we should have one that might more aptly be compared with Parliament. Such a change would enable it to accomplish all its desires that were obviously for the good of both the profession and the public, thus endowing it with a power that no one will assert it now enjoys, seeing its repeated failures to obtain an amended Medical Act.

I ought not to omit to mention that some of the corporations have acted in a more or less liberal spirit in this matter.

Thus, Dr. Paget stated, last year, that every member of the University of Cambridge—that is, I presume, everyone on the Parliamentary Register—was entitled to a vote at his election; and we may conclude, from there never having been a contest, that the mass of voters consider him the most eligible person for the office. Certainly his speech last year, as well as his general course in the Council, go far to prove to the profession the wisdom of the choice made by the University of Cambridge. The position of Dr. Paget should also reassure those who fancy that the enlargement of the constituencies would lead to a deterioration in the quality of the representatives.

Further, the two Royal Colleges of Edinburgh allow their *Fellows* a voice in the elections, as does also the London College of Physicians. I have yet to learn that the gentlemen who represent these bodies are in any respect inferior Members of Council to those deputed by smaller constituencies, and I hope they will not be found unwilling to give a vote to their members and licentiates.

The London College of Surgeons refuses even its *Fellows* a vote, and the exclusive example is followed by other bodies. The signs of better times are, however, increasing, and we may hope the day is not distant when all such wrongs shall have been swept away.

But—to come to the conclusion—since the Council is unable to obtain a new Act of Parliament, or to do much it might otherwise wish, you will naturally ask my object in addressing you at this crisis. I have not ventured to trouble you without a distinct aim, and, as I hope you will find, a practical one.

I desire to urge on the Council to attempt to amend its own constitution. I would have it boldly put itself in harmony with the profession, and proceed to point out the method of doing so.

I have explained above that an extension of the franchise of each corporation, in the election of its representative, would accomplish this desirable end. I have hinted that in some cases the usurpation of the governing committees has been illegal, and that redress might possibly be sought through the Courts, while a new Act of Parliament may be another mode of effecting a change. It would, however, be far better for the Council to act itself, and this it may do without consulting lawyers or waiting for legislation. In the session about to open it may do much; it may accomplish, unaided, the great re-

form on which I have insisted. For this reason I ask your assistance in submitting the following suggestion at an early sitting, so that it may have the benefit of full discussion, and the profession may know in whom to trust.

Granted, that the Council has of itself no power to dictate to each body what it considers the law; granted, even, that the Council as a body do not accept my view of the law; if only they think such a change desirable, let them distinctly say so. It cannot be supposed that in these days the corporations would all defy public opinion, and refuse a measure of bare justice recommended by the Council. Other recommendations of the Council have been listened to, and so, probably, would this be. If anybody were recalcitrant, other means might be tried.

I would suggest, then, that the Council pass a resolution of this kind:—

That in the opinion of this Council, each of its members should represent the whole of the interests of the University or other Corporation for which he sits, and, to secure this end, should be elected by those who hold the degrees or diplomas of such University or Corporation.

Such a resolution being passed, placed on the minutes, and officially communicated to the various bodies, would, it is to be hoped, at once be acted upon. Without any appeal to courts of law, or any intervention of the Legislature, we may believe that those who now choose would, after such an expression of opinion, relinquish a share in the selection to their fellow-graduates or fellow-members and licentiates.

It has been objected to my scheme, that there would be some difficulty in collecting the votes of such scattered constituencies. The reply is, that nothing could be simpler—nothing could work better, than the plan of election by voting papers adopted in the election of members of Parliament for Universities. In the Universities the constituencies are already in existence, and have proved satisfactory. The corporations mostly publish lists of their members or licentiates, and those lists would be recognised as the registers. This shows how much easier would be this mode of representation than one making territorial distinctions, long the bane of the profession, when they existed for other purposes, but now happily abolished. The constituencies are ready made, the registers exist. To those constituencies, I repeat, the Legislature intended to entrust the election of the members of the General Medical Council.

One more objection has been put forward—viz., that some men would, by my plan, obtain two or three votes, or even more—one for each corporation from which they had obtained a qualification. I see no objection to this. The doubly-qualified practitioner would have more influence than his singly-qualified neighbour. This might tend to elevate the profession, but could not have an opposite effect; and the extra vote would be but a slight return for the toil and expense incurred, and a slight recognition of the status conferred by the additional diploma. It is not considered objectionable for landowners to have votes in several counties for members of Parliament; and I see no reason why a practitioner should not vote for his University and for his College or Colleges as well.

Asking you to bestow upon the whole subject some of your own lucid judgment, and to submit my suggestion to the Council,—I am, Sir, yours faithfully,

PROSSER JAMES, M.D.

EXTIRPATION OF THE UTERUS FOR COMPLETE PROLAPSE.

PROF. LANGENBECK, of Hanover, has recently performed the operation upon a woman forty-eight years of age, who has suffered from prolapse since the birth of her first child, eighteen years previous. She had borne nine children since then. The result was a good one. The patient removed the ligatures herself from the eighth to the tenth days. The operation was performed on the 15th of May; on the 29th she left her bed; and on the 31st she took her first walk in the open air.—*Memorabilien.*

Notes on Current Topics.

The London Hospital.

WE wish to direct special attention to the report which we give in full of the proceedings at the distribution of prizes at the Medical College of the great East End Hospital. The speech of the President of the Poor Law Board is deserving attention, inasmuch as it evinces in the right hon. gentleman an interest in medical science and medical workers that has often been unobservable in his predecessors. The whole proceedings form a very important demonstration as to the present state of medical education and medical politics. Besides this they are of extra importance to those who may shortly be entering at a medical school, as they show how numerous are the prizes and how great are the opportunities for clinical study at the London Hospital. While in other hospitals men are glad to pay a high price for dresserships and other opportunities of real study, the London Hospital provides all such appointments free of charge; and so enormous is the field for clinical study that every student has unusual opportunities of filling appointments which are of the highest value, as they alone can fit for a future successful career.

Nearly Burnt Alive.

THE audience at St. James's Theatre have recently narrowly escaped the sight of a favourite *prima donna* being burnt alive. They saw her, indeed, enveloped in flames, and thrilled with horror as they gave her up for lost. Apparently the escape of Mdlle. Schneider from so awful a death was due solely to the presence of mind of several persons. Such presence of mind is too apt to fail at the right moment. It has often been pointed out that theatrical managers could render such a catastrophe impossible at the outlay of a few pence. If they will not see that the actresses' dresses are rendered unflammable they ought to be liable to punishment for manslaughter. We now appeal to Mdlle. Schneider, who has so nearly experienced the most dreadful fate, to refuse to play again unless her dresses and those of the other players are properly prepared. Such a refusal could not but be respected, and would be worthy of one whose courage in awful circumstances has been the theme of so much praise.

The St. Andrew's Association.

THE St. Andrew's Association spent a pleasant day at St. Alban's, according to the notification given to that effect. Many dined together in the evening, and all speak highly of the pleasure they enjoyed together.

The Water-Supply Report.

THE "trumpeting" journal that professes to be shocked at the naughtiness it perpetrates weekly, and was insolent when we predicted the nature of this Report, is now impatient for the publication of the evidence on which it is founded. That evidence will soon appear; and our "trumpeting" contemporary had better refrain from again being so enraged with us for venturing to have an opinion, as to lose all respect for decency, since we are about to venture on another prediction—viz., that when it appears it will confirm the report, and so be equally annoying to those who profess a desire to see it.

Some time ago a number of journals, misled by a few

individuals who had adopted the sensation hypothesis, gave currency to views that do not exactly accord with facts. The Report condemns those views, and the individuals in question are deeply annoyed. Long ago we told them the Report would do so; but they would not believe it. It would be very interesting to the public to be informed whether the delay in the publication of the Report arose from its being at first still stronger than it is; whether after our prediction the strongest pressure was not brought to bear to get its condemnation couched in milder terms.

The Registrar-General's Report of Births and Deaths in Ireland.

THE Quarterly Return for the months of January, February, and March of the births and deaths registered in Ireland has been issued.

The births registered amounted to 38,610, affording an annual ratio of 1 in every 35.9 of the population. The average during the corresponding quarter of the years 1865-8 was 38,537.

In twelve districts the number of births did not equal an annual ratio of 1 in 50 of the population.

Deaths.—There were 26,408 deaths during the quarter, a number affording an annual ratio of 1 in 52.5 or 1.90 per cent. of the estimated population. The average number of the corresponding quarter of the years 1865-8 was 28,224. The number registered in the following districts afforded the highest annual ratios:—Belfast, 1 in 25; Dublin, North, 1 in 33; Dublin, South, 1 in 37; Newtownards, 1 in 40; Lurgan, 1 in 41; Dungarvan, 1 in 42; and Clonmel, Wexford, and Londonderry, 1 in 43. In the following districts the deaths did not equal 1 in 80 of the population:—Manorhamilton and Cootehill, 1 in 82; Boyle and Galway, 1 in 83; Longford and Abbeyleix, 1 in 84; Bawnboy and Carrick-on-Shannon, 1 in 86; Oughterard, 1 in 87; Borrisokane, 1 in 90; Clifden, 1 in 91; Tuam, 1 in 94; Ballinrobe and Ballyvaghan, 1 in 95; Glin, 1 in 96; Dunfanaghy, 1 in 98; Ballinasloe, 1 in 99; and Newport (county Mayo), 1 in 113. It is evident from the foregoing figures that the registration of births and deaths is very imperfect, the annual ratio of births to the estimated population in England being about 1 in 29 or 30, and of deaths, of 1 in 44 or 45; whilst in Ireland, according to the present return, the ratios are—for births, 1 in 35.9; and for deaths, 1 in 52.5.

Though the deaths registered during the months of January, February, and March were 1,816 less than the average number registered in the corresponding period of the years 1865, 1866, 1867, and 1868, yet the amount of illness throughout the country was very considerable. Affections of the respiratory organs were most prevalent, and caused great mortality, especially among the aged and those of tender years. Of zymotic diseases that which proved most fatal was scarlet fever.

Of the 13 deaths registered in the Drumquin District, Castlederg Union, 9 resulted from scarlet fever. Many other instances might be adduced in proof of the sad ravages committed by this disease.

Several of the Registrars refer to the prevalence of whooping-cough, measles, and croup, the last named disease having been met with most frequently in the South-Western Division. In the Castledown District, Castledown Union, of the 37 deaths registered 7 were as-

cribed to croup; in the Carrigaline district, Kinsale union, 5 out of the 18 deaths registered resulted from croup; in Skull district croup caused 6 of the 32 deaths registered.

Several deaths occurred in Dublin from that disease which has received many designations, such as cerebro-spinal fever, cerebro-spinal arachnitis, purpuric fever, &c. Death, however, took place in some instances without any purpuric complication. Most of the persons attacked were under twenty years of age; the majority were males.

The Registrar of Dundalk states that "During the past quarter the locality has been visited by an epidemic of cerebro-spinal fever; 23 cases have appeared during the quarter, of which 11 have been fatal. In no instance have I been led to believe that it was by contagion." The Registrars of Louth and Dromiskin report that in each of their districts 1 death was caused by "Black death." The Registrar of Castleisland union records "one case of malignant purpura, which terminated fatally within twenty-four hours." One death from acute glanders occurred in Letterkenny.

The Small-Pox at Melbourne.

It is gratifying to be able to announce that all apprehensions with regard to the spread of small-pox seem to have subsided in the public mind, and that the dreaded plague has, for the present at least, almost disappeared, only one new case having recently occurred. In the meantime, the exertions of the central and local boards of health have not relaxed in bringing about an improved system of sanitary regulations in the city and the several suburban districts. These efforts have had the most beneficial results. The River Yarra, there is every hope, will not much longer be polluted by feculence and obnoxious deposits from drains and manufactures established on its banks. The question of the sewerage of the city has forced itself upon the City Council, and cannot fail of being at no distant date seriously taken up and something done to materially improve it. Cesspools are carefully inspected, and the back lanes and slums regularly cleaned, and disinfectants applied wherever it is deemed necessary. Thus many of the predisposing causes of epidemic have been removed, and the city and the public health greatly benefited by the change.

Cholera in India.

ACCOUNTS continue to reach us of the great havoc cholera is making in Raipore. We learn from a correspondent that no less than sixty-three deaths occurred on the 27th ult. in the town of Raipore. We have also news from Nursingpore under the same date, and the writer informs us that matters there too present a very gloomy aspect indeed. The people of that district are in a great state of alarm and excitement. Returns show that out of 220 cases 160 deaths took place, and among the fifty European railway employés five were attacked, and all succumbed to the disease. Our correspondent also gives a sad account of the sudden death from the same disease of the district engineer, Mr. Smythe. This gentleman was a guest at a farewell dinner given on the occasion of the departure from that station of Dr. Raye, civil surgeon, on the 20th of last month. Mr. Smythe was an universal favourite, and by his gaiety and light-heartedness was the life and soul of the party. He was a particularly abstemious man. The next

morning he took ill and died the same day. His untimely death has cast a gloom over the small social circle of Nursingpore.—*Central India Times*.

Naval Medical Service.

THE following notice has been issued from the Admiralty:—"With reference to the regulations of November 4, 1868, relative to the appointment of assistant-surgeons in the Royal Navy, the Lords Commissioners of the Admiralty hereby give notice that, in consequence of the large number of applications for these appointments, and the small number of vacancies, a competitive examination similar to that which is established for assistant-surgeons in the Army will be held on August 9, 1869. Candidates must present themselves at the office of the Director-General of the Medical Department of the Navy on August 5, bringing with them the various certificates of qualification specified in the circular above referred to, when, should they be found in all respects eligible, they will be permitted to appear before a Board at Chelsea for examination in the following subjects:—Anatomy, surgery, physiology, or institutes of medicine, practice of medicine, chemistry, *materia medica*, midwifery, and botany. No change is otherwise made for the present occasion in the regulations relative to the examination of candidates for the appointment of assistant-surgeon in the Royal Navy of November 4, 1868.—By command of her Lordships, W. E. BAXTER, July 21, 1869."

Lime-Water in the Treatment of Bright's Disease.

KUCHENMEISTER recommends in the treatment of Bright's disease and of nephritis after scarlatina the use of large doses of lime-water, theoretically from its having the property of dissolving proteine. *Lyon Médicale* details the treatment, and says that caustic lime in solution, or any of the soluble salts of lime, will answer equally well. He has seen the urine increase from 30 grammes to 120 the first day, 180 the second, 300 the third, and up to 1,020 the seventh day under this influence; sometimes a slight hæmorrhage necessitates the disuse of this treatment; but the quantity of albumen in the urine sensibly diminishes.

Remarkable Case of Catalepsy of Fifty-four Days' Duration.

THE *Presse Médicale Belge* narrates the following:—A stout girl, aged twenty, menstruating since sixteen years of age, but suffered at each period severe abdominal pain, with a scanty flow. When seventeen years of age she got a convulsive attack, which lasted eight days; since that date she frequently suffered from similar attacks, which, however, only lasted about a quarter of an hour. On the 24th December, 1868, being accused of a theft, she threw herself into a river, from which she was soon extricated, and restored with much difficulty. She had fits of trembling, violent movements of the limbs, sighing, and distress; she attempted, when asked, to show her tongue, but could not; the pharyngeal muscles were paralysed. On the next day loss of consciousness was complete; the jerking of the limbs continued; twitching of the facial muscles; respiration very

feeble; pulse rapid; urine passed involuntarily; the eyes often remained open for two or three hours without winking; the temperature was 30° R., and the pulse as high as 130. In this condition she remained seven weeks. The face was without the least expression, the eyes were open for hours, and the whole muscular system was relaxed, the limbs remaining in whatever attitude they were placed, and the mouth open till closed by the by-stander. Fainting fits came on, and the temperature of the body fell so as to simulate death—at one time she was absolutely thought dead. After the eighth week spent in this condition, she suddenly revived, and gradually was restored to health, and declared that she was perfectly unconscious of the immersion, and of her having remained for so long a period in this insensible state.

Ileus treated by Injections of Seltzer-Water and Tobacco.

A YOUNG woman of 25, whose case is detailed in *L'Union Médicale*, was recently admitted to the Hotel Dieu, suffering from the usual symptoms of internal strangulation in a well marked and severe form.

Feb. 17.—Castor-oil combined with croton-oil was given without effect. By means of a seltzer-water apparatus attached to a long œsophageal tube, a gaseous injection was administered, after which the bowels were moved.

20th.—The symptoms being now very urgent, it was determined to give another injection of seltzer-water and then one of tobacco.

20th.—Two stools had been produced by the enema.

21st.—A second tobacco enema administered.

22nd.—A third was now given, the symptoms being much relieved. From this date she made a favourable recovery, and was discharged, cured, 13th March.

Another girl, aged twenty-five, was admitted, suffering acutely from symptoms of intestinal obstruction. Purgatives were tried without effect.

April 15.—A tobacco enema was administered.

16th.—The second tobacco enema administered. The patient was not suffering so much, and in the evening got decidedly better.

18th.—Another tobacco enema was given.

19th.—The symptoms showed signs of severity. A tobacco enema was administered, and in the evening of the same day another tobacco enema was given.

20th.—The belly was more swollen, and pains more severe; tobacco smoke was now introduced into the intestines by the apparatus of Mathew's. She got under its influence suddenly, and caused much anxiety by the consequent prostration, which was treated by coffee and electricity over the heart. From this date till June 2 the patient made a gradual recovery, the symptoms of obstruction having yielded directly after the establishment of the influence of tobacco.

Prosecution under the Medical Act.

IT is only a short time since that a noteworthy prosecution under the Medical Act occurred at Wolverhampton, and we call attention to it as exemplifying in a marked degree the uncertain and unsatisfactory state of the law. A person named Clews, who keeps a chemist's shop in Darlington street, in that town, was summoned for three

offences under the Medical Act. The first charged him with having falsely pretended to be a surgeon; the second with using his name as assistant surgeon, as a description implying that he was recognised by law as surgeon; and the third summons stated "that he being a person not duly qualified under the Medical Act did unlawfully hold an appointment." In support of these charges the evidence of patients whom he had attended was adduced, and the secretary of the People's Family Life Assurance Sick and Benefit Society proved that Clews had acted and received payment as its medical officer. Strange to say, notwithstanding evidence apparently so conclusive, the first and second summonses were dismissed, and the third adjourned. At the adjourned hearing the third charge was withdrawn (no doubt in despair of obtaining a conviction) on the understanding that Clews gave up his appointment to the society. The stipendiary magistrate, while concurring in this settlement, admitted with much candour that the correctness of his decision on the first and second summonses "was not so clear as it appeared to him at first." Not so clear! What a grim satire on the justice under which the medical profession has so long groaned! No wonder we are ready to sign memorials asking for a new Act of Parliament, when the Medical Act for 1858 for which we have paid so dearly is worse than useless; nay, more, is absolutely hurtful by pretending to protect the profession and the public from unqualified pretenders, while in reality it permits them to grow and flourish under its legal shade. Unsatisfactory as the Wolverhampton case is in itself, it will do good as the last drop in the overflowing cup of bitterness from which we expect the reformed Parliament to save us.

THE monthly dinner of the Medical Club is this evening (Wednesday, the 28th). Mr. Saunders in the chair.

DIRECTOR-GENERAL SIR G. LOGAN visited Netley Hospital last week.

THE British Medical Association is just now holding its annual meeting at Leeds. The meeting commenced yesterday, and extends through this week.

THE Justices have determined to bear no part of the expense of introducing the Contagious Diseases Act into Bombay.

MR. COWASJEE JAHANGEER READYMONEY, C.S.I., has made a present of Rs. 18,000 to the city of Bombay, for the purpose of raising fountains, &c.

THE Medical Society of Washington having given a more than two-thirds vote against the admission of a coloured M.D. named Tucker, it is threatened that on the reassembling of Congress, the Act incorporating the society shall be so amended as to give negroes all privileges of full membership, despite the wishes of the present members.

THE *Turin Gazette* states that owing to the sudden heat following upon comparatively cold weather, there has been great mortality at the camp of Sonna. Twenty-four men died, it is said, in three days, and in a single day one hundred were seized with illness. It is expected that owing to

these circumstances the camp will be broken up. At Bagnoli several soldiers, while returning from a review, were so overpowered by the heat that they fainted, and one of them has since died.

THE *Agra* paper records the appearance of cholera there. On the 9th, 10th, and 11th, seven cases occurred in the right wing of the 40th Native Infantry, of which four terminated fatally. At the same time there were perhaps a dozen cases in all towards the city and the Civil Lines. The wing of the 40th went into camp on the 12th. Since then it has been free from the disease, and no other cases have occurred in cantonments. In the city there have been a few, but they are considered "doubtful." H. M.'s 77th and the Artillery have not had any cases.

It has been decided by Government to commence the experimental manufacture of salt in Oudh, and it was intended that the experiment should have begun at once. But the Chief Commissioner and Mr. Hume, Commissioner of Inland Customs, to whom the consideration of the matter was left, have decided, in consultation, that the season is too far advanced to attempt operations with success. The Chief Commissioner has been informed by Government that it is considered important that operations for the manufacture should be vigorously commenced immediately after the rainy season, and that before the 1st of February next some reliable information regarding the prospects of the experiment should be submitted to the Government of India.

A CORRESPONDENT of the *Delhi Gazette*, writing from Nusseerabad, under date the 8th instant, states that cholera broke out among "The Royals" on the night of the 6th instant. Up to the evening of the 7th there had been eight cases with two deaths; during the night another case and one death. The Artillery and Native Infantry were free from the scourge. There had been cases in the bazaar and surrounding villages during the previous month, but it had not assumed an epidemic form. A letter written on the following day, the 9th, reports that since the previous morning there had been six additional cases among the Royals, with three deaths. Altogether up to the morning of the 9th there had been fourteen cases with five deaths.

THE *Friend of India* says:—Heat such as we have not known in the past fifteen years, has been making life in the plains of India an intolerable burden. When the thermometer rises above 88°, as it does for six weeks every year in Bengal, life becomes a mere toleration of existence. But this year there have been few afternoons of late which have not seen it at 96° and even 97° in the coolest rooms. The cyclone of the 9th was thought to have brought the great monsoon, but it has only added moisture to heat, and made matters worse. The fields, however, are alive night and morning with ploughmen, and the villagers, who hide themselves in the dense vegetation of Bengal, having rebuilt their huts of mud and bamboo, are cheerful.

Not so in the feudatory States of Central and Upper India. Things are still as quiet there as sunstroke and cholera will admit. People on the brink of starvation die quietly. Many have died—how many we shall perhaps never know. Whole villages in some of the States have been swept by cholera. The Marwarees, struggling along

the Neemuch road on their return to Rajpootana, have left their dead on the highway. Many corpses were thus seen a few weeks ago, but now there is a lull. Towns in Holkar's territory have suffered much. Death has been moving all through Bhopal also, and in the Goona district the ravages have been great. In Bundelkund, where the famine has been sorest, cholera has been less active than in other places, but there is a time of trial yet to be tided over, between this and the rain crops. The native States have been saved so many horrors that seemed inevitable in the famine, which was so nigh, that a correspondent writes to us, "We may well bear the burden we have and strive by supplying food and work to meet the future." Charity has been great and general. Had it not been so Bundelkund and Gwalior would have been depopulated.

THE LONDON HOSPITAL AND MEDICAL COLLEGE.

On Monday, the 19th inst., the Prizes were distributed in the Anatomical Theatre of the Medical College of the London Hospital. The Right Hon. G. J. Goschen, M.P., President of the Poor-Law Board, occupied the chair, surrounded by nearly the whole professional staff of the Hospital, and most of the Professors in the College.

The CHAIRMAN.—Gentlemen, we are met here to-day to present the prizes to the successful students, and a very gratifying meeting it is on that account. What great pleasure it gives me personally to take part in these proceedings I shall have occasion to express when I address those few words to the students which it is customary for the Chairman to address to them on these occasions. But, in the first instance, I will ask the Dean to read the Report (applause).

The DEAN (Mr. RIVINGTON) then read the Report:—

Mr. CHAIRMAN and GENTLEMEN,—It will be satisfactory to the friends of the London Hospital Medical School, which was the first complete Medical School in the metropolis, and which is about to conclude its eighty-fourth academic year, to learn that its condition was never more prosperous than at the present time. The number of new entries for each of the last two years has been more than double the average number for the six years immediately preceding them, and not far short of the number of entries in 1860, when forty-eight gentlemen enrolled themselves as students of the school. The cause of so large an entry in 1860 was of an exceptional character, consisting in the fact that 1860 was the last year during which gentlemen could enter upon the course of study for the medical profession without exhibiting their attainments in the subjects of general education; and hence, in this year of grace, all those whose natural modesty rendered them diffident of success in the face of an untried ordeal, and all whose training had proceeded in other directions than those required by the General Council of Medical Education and Registration, took advantage of the dispensation, and flocked in at the unguarded portal of the medical profession. This fact is here mentioned, because the recent increase in our entries presents a contrast with the increase in 1860, in that it appears to be due not to any exceptional cause, but to conditions which ought logically to render that increase permanent. As a matter belonging to the educational history of the School, we are able to point to large additions lately made to the advantages offered to students of the Hospital and College. In 1866 the west, or Alexandra wing of the Hospital, was completed and opened, and the number of beds, which had previously amounted to 445, became more than 500, and has now reached a total of 570, thus following closely in the wake of the two larger metropolitan Hospitals, St. Bartholomew's and Guy's. But, together with this increase in accommodation for patients, and consequently in material for instruction, there has been that which is of equal, and, I think, of greater importance, an improvement in the internal arrangements of the institution. The whole of the rooms for the examination and treatment of out-patients have been remodelled, and made light, comfortable, and commodious—epithets expressive of qualities often "conspicuous by their absence" from similar departments. Another ward has been set apart for children, more especially for the

reception of medical cases. Male and female wards for ophthalmic diseases were opened last November in a secluded part of the building, and have been found of the greatest advantage. A spacious attic, fitted with every appliance for examination and treatment, has been devoted to Local Contagious Diseases; and the Hospital has thus been voluntarily aiding the enlightened policy which recent years have seen adopted towards a class of the community, it may be "more sinned against than sinning," whose freedom from disease is demanded, apart from considerations of a Christian humanity, for the protection of the innocent, and as a main factor of the potential improvement which preventive medicine can effect in the health of the community at large. Special Departments have been instituted for the treatment of patients with Diseases of the Eye, Ear, and Skin, and special arrangements made for Diseases of the Throat; and—not to mention other alterations and additions to the old building since 1866—we may point to the transformation of a large repository and small post-mortem examination room into a smaller repository and a pathological theatre—the best, we believe, and the largest in London; representing to us, possibly, that in proportion as medical science is fostered and cultivated, in the same proportion, within the limits of human power, shall we obtain control over disease and death. Sir, while the origin of some of these improvements may be fairly attributed to the advice of the medical staff, the main credit of design and execution must undoubtedly be awarded to our House Committee, which includes gentlemen whose single-minded devotion to the interests of the Charity is above any praise of ours, and which is fortunate in possessing in Mr. William John Nixon a counsellor and administrator of ripe experience and ability, whose constant aim it is to keep pace with the progress of the time, who is ready on all occasions to promote the comfort and convenience of the officers of the establishment, clerical, medical, and lay, and, so far as his sense of duty to the Hospital permits, to further the suggestions for development which have been offered, and offered, we trust, in his opinion, not too sparingly by the Medical Council of the School.

It is plain matter of fact to say that, whatever abatement in our desires in regard to the School may be necessitated by the pecuniary position of the Hospital, there is seldom, if, indeed, there is ever, any refusal to provide instruments or appliances for the scientific treatment of disease whenever they may be required by the medical staff. All requisitions of the kind receive immediate attention; so that if it be true, as a medical paper (the *Lancet*) stated, a week or two ago, in a mis-leading article, that every general hospital in London is lamentably deficient in the means necessary for the scientific treatment of disease, it ought at least to be understood that the responsibility at the London Hospital rests not with its House Committee, but with its medical staff, who have been smitten, day after day, with a marvellous blindness to a deficiency, which, though invisible to the naked eye of the near observer, has been clearly obvious to the telescopic vision of stationary critics.

Concurrently, Sir, with the improvements at the Hospital, to which I have been able to do but scanty justice, important measures have been adopted by the Medical Council for the welfare of the School. Our administrative organization has been consolidated; a friendly supervision has come into fashion, including a conscientious systematic and scientific registration of attendance on lectures. The number of appointments open to students has been increased, and to some have been attached a *doubleur*, which does not diminish the pleasure and profit resulting from the discharge of duty. The Prize System, which was abandoned in 1857, has been revived, but with this difference: that, instead of the Gold and Silver Medals then in vogue, and which were almost useless—talents concealed in morocco cases—unless exchanged for books or microscopes, or, as they often were, for the current medium—Scholarships and Money Prizes have been given, and found better suited to the wants and practical tendencies of medical students. In 1863, Mr. Duckworth Nelson, a former pupil of the School, in grateful recollection of the advantages here received, placed £100 at the disposal of the Medical Council to found a prize. The interest of this sum constitutes the Duckworth Nelson Prize, which we devote to the encouragement of practical work in the Hospital, by making the award depend upon an examination, of which the recognition of disease and its products forms the chief element. The first prize was given in the Session 1865-66, and in the same year the Council offered two scholarships, one for Osteology, and the

other for Anatomy, Physiology, and Chemistry, the competition being limited to first-year students. One reason for this limitation was, that, unfortunately, none of our too numerous Examining Boards, which are occupied in conferring the inferior qualifications, tests a medical student's knowledge until the end of his second winter session; and hence there are no inducements, but a sense of duty and a thirst for knowledge, to encourage work in the first year. The first year is often wasted, and it was hoped that, by offering these scholarships, we might be able to exercise an industrial influence over some, at least, of the students, who would otherwise indulge in relaxation. At the time of the institution of these scholarships the entries were not over-abundant, and the receipts were proportionately small; and, inasmuch as the whole of the working expenses connected with the maintenance of the School and College are taken out of the fees, £45 were as much as we could afford. But, on comparing our position with that of other and larger Schools, we found that they all gave away considerable sums in scholarships or exhibitions. King's College gives yearly £350 in money, Guy's £265, St. Bartholomew's £260, and University College £280, and to a large extent some of these sum represent endowments by friends and governors of the institutions. We determined, therefore, to make an effort to raise a fund for scholarships, and, wishing to do honour to a Governor, whose name with us is a household word—Mr. Thomas Fowell Buxton, the Treasurer, and lately Chairman, of the House Committee of the Hospital—we gave to the prospective scholarships the name of the Buxton Scholarships. Our efforts have so far proved successful, that we have obtained nearly the £1,000 which we wish to raise. £500 of this sum were most liberally given by the House Committee of the Hospital. We are, therefore, enabled to announce two Buxton Scholarships for 1870, to be given to the students who pass at entrance the best examinations in the subjects required at the ordinary preliminary examinations in general education. One of the great objects for which medical reformers are striving is to elevate the standard of general education among those who intend to study for the medical profession, and for this reason, and in order that the east end of London may be adorned by a larger number of students with minds already cultivated, and further, in order to place the School on an equal footing with St. Bartholomew's, Guy's, University, and King's College, we came to the foregoing decision. Meanwhile, to fill the vacuum which would otherwise exist in the rewards for the approaching Session, the Medical Council will give out of the fees two similar scholarships in October next. Last year the three Hospital Scholarships for the three cardinal branches of practice, Medicine, Surgery, and Obstetrics, were substituted for the gold medals given by the Governors of the Hospital. To complete the present list of prizes, it should be added that in 1867 the House Committee determined to give a stimulus to the work of dressing the surgical out-patients, and placed £60 at the disposal of the Medical Council, who divided the sum into six prizes, three of £15 and three of £5. There are now twenty-four pupils dressing in the out-patient rooms.

From this statement it will be gathered that the money prizes awarded at the School will amount, in alternate years, to £215 and £225; and when it is remembered that the appointments open to students at the Hospital are very numerous, that, thanks to the House Committee, they are on a very liberal scale, that some of them have salaries attached to them, that there is no fee to pay for any of them, and that all the officers residing in the Hospital receive their rooms and rations absolutely free of charge, we think that the conclusion may be drawn that our rewards will bear comparison with those offered elsewhere. The only point in which we are at present deficient is, that we are offering no class prizes other than honorary certificates. There is an absence from the table, at which we are rejoiced and honoured by your presence, Sir, to-day, of the handsomely bound volumes, which would give it greater variety of charm. The fact is, that there is a limit to the exchequer, and bearing, as we have decided to bear in the ensuing year, the weight of additional scholarships, we must be excused for pausing to observe what our receipts will be, and for not pushing further our loyal adoption of the prospective and slightly hazardous principle on which the income-tax is to be levied.

There is one other branch of progress to which it is my duty, before sitting down, to make allusion, and it is one as to which the Medical Staff of a Hospital distinguished as a field for observation and practical study must feel peculiar satisfaction. I refer to the development of the arrangements for teaching stu-

dents objectively a knowledge of diseases. In all the departments of the Hospital, both general and special, in the wards, medical, surgical, and obstetric, in the operating theatre, in all the out-patient rooms, the work of practical instruction will be carried on. The chief features of the cases coming under observation will be brought before the students, and impressed upon their minds so far as our teaching abilities and physical capacities will permit. There will not be a single division of practical study for which arrangements have not been made. The additions this year have been the institution of Clinical Medical Wards on a plan similar to that which has helped to give Guy's Hospital its reputation as a School of Clinical Medicine; a Department for Practical Pharmacy, and provision for the study of Diseases of the Mind. The Council has accepted a most kind and liberal offer of Dr. John Millar, the Medical Superintendent of Bethnal House Asylum, a few minutes' walk from the Hospital, to permit students of the Hospital to attend, without payment, the practice of the Asylum daily, between the hours of ten and twelve, when Dr. Millar will have the greatest pleasure in giving them instruction in mental diseases.

To sum up the matter: we shall be affording a daily exemplification of the principle generally accepted by everybody except half a score of licensing corporations keeping at a respectful distance behind professional opinion—namely, that students cannot learn to recognise disease and to treat it without having seen it, and therefore that the best mode of ascertaining whether they are fit to recognise it and treat it, is to place it before them and ask them to state their opinions on its nature and treatment. So far is this principle from being recognised, that the greater number of the nineteen licensing bodies altogether abstain from taking the student to the bedside, or bringing cases to the student and requiring him to describe and explain the symptoms and the methods of treatment. At present, therefore, we are in advance of the Licensing Corporations.

This, then, Sir, is the condensed catalogue of the measures which have been recently adopted, and which have been placed before you far less effectively than they would have been by the senior member of the staff, Mr. John Adams, for thirty-seven years Lecturer on Anatomy at this School, or by Mr. Jonathan Hutchinson, my immediate predecessor in the office which has now fallen into comparatively feeble hands, and in which he rendered so much good service to the School which his varied powers adorn. But even this catalogue would be incomplete if I did not add, in conclusion, that we are preparing for another effort. The room adjoining this theatre is the Anatomical and Pathological Museum. It is quite as full as it conveniently can be, and we are anxious to enlarge it. The architect of this building, whatever may have been his merits, from which I should be sorry to detract, was not gifted with the prevision which could foresee the expansive capacity of the School. This fabric, even more than that House of which you, Sir, are an eminent member, is remarkable for its want of elasticity, and, in order to enlarge it, it may be necessary to diminish the beauty of its outline, and mar the symmetry of its proportions. The total expense is estimated at £2,000. These considerations, however, can weigh but little in the scale against the real wants of the School. There are museums at one or two of the other schools better than ours, and more largely supplied with educational resources. These schools, it is true, are, and have long been, richer than we are, and able to expend annually larger sums in their maintenance. But having regard to what we have been able to effect in a short time in other directions, and having this definite policy to guide us, that our School ought to be rendered complete in every department, so that in no one single particular may it present any unfavourable contrast with others, we shall hold on in the course which we have been steadily steering. Ready as we are, if our receipts increase, to devote a proportionately increased amount to the improvement of the School, we shall not be discouraged by that unfortunate deficiency of income which prevents a liberal House Committee, while approving and aiding our general plan, from making us an immediate pecuniary grant; and believing, as we do, in the stability of the School, even when a Government, released from grappling with "gigantic issues," shall have earned our lasting gratitude by extending the measure of justice to a profession destitute of a voice in the election of the Council which is supposed to regulate its affairs—believing that the School will survive the long-desired and much-needed change, which shall give us, in place of many minimum qualifications, represented by a variety of puzzling alphabetical combinations, and varying in the degree of

their unreliability, a single complete qualification to practise, which shall be a real guarantee of competency to treat "all sorts and conditions of men"—not the unsuspecting citizen only, but the members of Her Majesty's Army and Navy, who have now to be carefully protected from the Licenses of the Corporations—believing that the School will survive the almost inevitable diminution in the number of medical schools and other changes in our educational system—we shall persevere together with one heart and mind, and, in the spirit of those who founded and fostered it, we shall "deem nought done whilst ought remains to do." (Great cheering.)

Dr. HERBERT DAVIES.—I have great pleasure in introducing to you two gentlemen who have won respectively the gold medal of last year and a scholarship of £20. There has been a little alteration in the arrangement under which I shall have to present to you, first, Mr. Edmund Vials, on the principle of *seniores priores*. By some irregularity last year we were not able to give him the Gold Medal at the proper period, but I have no doubt he will receive it to-day, with greater gratification at your hands. With respect to these clinical medical prizes, I need not tell you, after the exhaustive Report of the Dean, that they are the most important which this School can offer. The teaching of this School, and of all medical schools, culminates in clinical medicine, surgery, or obstetrics, and you can readily understand that all the aim and object of the teaching of this School is to enable students to learn, practically, at the bed-side, the diagnosis of disease and its treatment. Without troubling you with any further remarks, I will now simply present to you Mr. Vials and Mr. Ashley Barrett as the recipients of these prizes.

The CHAIRMAN.—Mr. Vials, I have great pleasure in presenting you with this Gold Medal, and I know that its fate will not be that which was so humorously sketched by the Dean; but it will remain in your hands, I trust, for many years, as a memorial of the time which you have so successfully spent at this Hospital. I see on the medal there is a picture of this Hospital, founded, as its title tells us, by "Voluntary Contributions." In that Hospital you have been a successful, and, I am sure, an honoured student, and I have much pleasure in presenting you with that which I know you will value as a reward of your labours.

Mr. Ashley Barrett, I am very happy to present you with the cheque which has been so liberally given jointly by the House Committee and by the Medical Council; and also with your certificate, which tells how profitably you have spent your time in this Medical School.

Mr. CURLING.—I have the pleasure, Sir, to introduce to you Mr. S. Mackenzie, to whom has been awarded the £20 Scholarship; and I think it is right to state that he has not gained this without a very keen competition. This has been acknowledged by an honorary certificate having been awarded to Mr. O. Baker. Mr. Mackenzie is well known here as one of the hard-working students, and he, I have no doubt, will reap his reward.

The CHAIRMAN.—Mr. Mackenzie, I have great pleasure in presenting you with the prizes you have gained. May you continue that keen competition which you have had to undergo here, in your future life, to the advantage of the profession and the public. Let me add, that I hope there may always be such keen competition amongst those who adorn the medical profession. (Loud applause.)

Dr. PALFREY.—I have the pleasure, Sir, of presenting to you Mr. William Leapingwell, who gained, after a very creditable examination, the First Scholarship for Midwifery in this School. I can only say he is a student we feel proud of; and I hope every year we may be able to present to you gentlemen equally successful and equally creditable to the Institution. (Applause.)

Dr. CLARK.—I have great pleasure in introducing to you Mr. George Ernest Herman, who is the successful competitor for the prize in Practical Medicine and Surgery. I may just state that this prize was competed for by three gentlemen, all of whom are upon our prize list. Mr. S. Mackenzie, Mr. Ashley Barrett, and Mr. Herman, and I think I am but barely representing the feeling of my co-examiners when I say that the answers to the examination, which you will see is a practical one, were about the best we had ever received. In fact, the physicians themselves were unable to settle who was the successful competitor, and, as is sometimes the case at this Hospital, we were obliged to go and consult the surgeons; and it was they who ultimately by their opinion turned the scale. I notice, and perhaps you, Sir, as a statesman, will notice, that the word "practical" only occurs twice

in the list; but I can assure you that although great part of our education here is necessarily didactic and descriptive, practical teaching occurs everywhere in this Hospital and School. (Applause.) I am very happy to find that the prize falls into Mr. Herman's hands, for it is no indelicacy for me to say of him—having seen him constantly in the wards—that he is one of the most diligent students we have the happiness to possess; and his quiet, modest, gentlemanly, and unobtrusive manner—qualities very useful sometimes in medical life—have endeared him, I may say, to all his teachers, as well as to myself. (Applause.)

The CHAIRMAN (addressing Mr. Herman).—I am sure by the expressions of approval I have heard that the whole of those who are present here are as happy to see you receive this evidence of your merit, as I have been to place it in your hands. (Loud applause.)

Dr. PALFREY.—Fortunately, Sir, the certificates you are about to present to these gentlemen combine the necessary qualification for very excellent pupillage. When I tell you that each of the gentlemen has attended from this hospital upwards of a hundred cases of midwifery, you will appreciate the amount of labour and work and of anxiety that has been involved in that attendance. I shall say no more than to tell you that the former of these gentlemen has been one of our very best clinical pupils that since I have had the honour of holding the position which I do in this hospital it has been our lot to receive. (Applause.)

Mr. HUTCHINSON.—Sir, I have the pleasure to introduce to you a batch of students who have distinguished themselves by zeal and diligence in their attendance in the out-patient department.

Mr. Edis, Mr. Moore, Mr. Parker, Mr. Beach, Mr. Fordham, and Mr. Vickers, were then presented with cheques and certificates by the Chairman.

Mr. ADAMS.—Sir, the Dean of the Faculty has very kindly requested me to introduce two gentlemen who obtained prizes in anatomy, the osteological prizes; and I do this with great pleasure, because although I was lecturer here for thirty-seven years (applause), I have not, as was stated by the Dean, had the pleasure of addressing a class in this theatre now for the last twelve months. But I will state this, that I have always found—and what I have found is corroborated by every day's experience—that if a man wishes to lay a good foundation for the practice of his profession, he cannot do better than lay that substratum by the study of anatomy. And I do not know that any department of anatomy is more important for a student to comprehend, and well understand, than the anatomy of the dry bones of the human skeleton. I, therefore, feel very great pleasure Sir, in introducing these gentlemen to your notice, who have obtained the osteological prizes; because I am certain that those gentlemen will, having laid that foundation, continue their exertions, and raise a superstructure of anatomy, which will eventually be of infinite service to them, when they come before us as Examiners in the Royal College of Surgeons, and more particularly when they come before us in that profession which I consider so arduous, and which is only facilitated in its practice by a strict study of anatomy. I have great pleasure in introducing to you Mr. Morgan and Mr. Lewis Mackenzie, the former for the £20 Scholarship, and the latter for the Honorary Certificate. (Applause.)

The CHAIRMAN.—Mr. Morgan, I have great pleasure in presenting you with this prize for Osteology, a study which is more difficult for us outsiders to understand, perhaps, than any other. But I can assure you that on that account we do not at all underrate its importance. On the contrary, it appears to us to have something magical about it, from the very difficulty which we feel adequately to appreciate it.

Mr. Lewis Mackenzie, I have now the pleasure to present to you the Honorary Certificate which you have gained in the study of Osteology. I understand that I shall also hear from Dr. Letheby that you two gentlemen have distinguished yourselves in another branch of medical science. (Applause.)

Dr. LETHEBY.—It is my duty, Sir, and my privilege I may say, and it certainly is a very great pleasure to me, to have to introduce to you Mr. Morgan and Mr. Lewis Mackenzie a second time for the Prizes which have been awarded in Anatomy, Physiology, and Chemistry. And now, Sir, it is necessary, perhaps, that I should say a word in explanation of the association, as it may here appear, of three very dissimilar subjects; as to why it is they are made collectively (being so dissimilar as they certainly are in their abstract nature) the subject of competitive prizes for anatomy, physiology, and chemistry: one of them, anatomy,

having for its object simply an inquiry into the structure of the human body, and the other two being branches of science that take cognizance of the movements of that structure and of the intricate molecular movements that constitute the phenomenon of life. Twenty years ago, or I may say, ten years ago, if anyone had said that Chemistry and Physiology would be found together hand in hand in pursuing an inquiry into the subject of any department of medicine, it would have been considered altogether foreign to the objects of such pursuits. For, Sir, while Physiology had for its object an inquiry into what was thought to be a peculiar force, commonly called vital force, taking cognizance of phenomena that were occurring in the human body, and thought to be so entirely different from the operations which were manifested by the action of common forces that it was regarded as the result of the action of vital force, and Chemistry taking cognizance only of the action of special forces whereby a new compound was formed—these two sciences standing so apart, upon distinct ground, have by the extension of their pursuits, come so together that they have at last come to be studied hand in hand in one kind of inquiry. Chemistry from this time forth can have no knowledge whatever of the physiological operation of the human body, without a knowledge of physiology: and, on the other hand, most assuredly, physiology can have no competent knowledge of the actions that are taking place within the human body, except through the aid of chemistry. (Applause.)

I look upon it, therefore, that the association of these subjects, as the subjects of a competitive examination will do good, not only in respect of Medicine, but in respect of the science of Chemistry. Already we have got to know, Sir, that most of the operations that are taking place in the human body are operations that are not due to the action of any special force, but that they are due to the action of natural physical forces; and the operation of the chemical forces. We have got so to know (and that may interest you in the political position which you occupy) the relation between food and force and human labour, that both in our workhouses and in our criminal establishments we shall, before long, be able to estimate the exact quantity and quality of food that is to be given in each particular case to satisfy the wants of the system.

But, irrespective of that, I say this—that medicine can never be looked upon as a certain, or even intelligible science, until it comes to rest clearly upon a large knowledge of chemistry as well as of physiology; and I hope, Sir, that the gentlemen who have been competitors for this prize will find that the knowledge that they have gained, in the course of their inquiries into those subjects, will be beneficial to themselves, not only in the treatment of disease, but in the understanding of the operations of the human body in their studies hereafter, and that it may lead them to investigate the subjects still further, so that they may be an honour to the profession the study of which they have entered upon. (Loud applause.)

The CHAIRMAN.—Gentlemen, I have great pleasure in handing you this prize and certificate. I can add nothing to the most interesting remarks that have been made by Dr. Letheby, beyond this, that it appears to me that you both have tried to illustrate in your own persons the close connection of those two subjects to which he has referred; for you both successfully competed for each in the one competitive examination. Mr. Morgan, possibly representing osteology, has been more successful than Mr. Mackenzie possibly representing chemistry. In the other the proportion of merit has been reversed, but Physiology and Osteology, in your persons, at all events, have been successful. I am very happy to present to you these prizes. (Applause.)

Gentlemen, having performed that portion of those duties which I have been very happy to undertake to day, of presenting the prizes to the successful competitors, I have now to do that which I believe is customary on these occasions—to offer a few remarks to the students generally. And, gentlemen, I am sorry that amongst all the discoveries of medical science, and amongst all those triumphs which Dr. Letheby has enumerated, there is one which medical science has never yet, as far as I have learned, been able to perform—and that is to pump ideas into an exhausted mind. (Laughter and applause.) Gentlemen, I wish that medical science could do that, or that it could give something like force to what may otherwise be an uncertain utterance. But medical science, successful in so many other departments of pathology, has not been able to achieve that yet—to give to a man appropriate ideas on every occasion when he would wish to have them. (Laughter and applause.)

I have come here to-day with great pleasure, answering an

invitation which the Medical Council forwarded to me, for more than one reason. In the first instance, I am intimately connected with the City of London, which is near to this Hospital. This Hospital represents the wants, or rather supplies the wants, of eastern London generally; but my connection with east London has not been the only reason why it has given me particular satisfaction to be here to-day. I happen to occupy a position in which I am continually brought in contact with the medical profession (applause), and I feel that, in many respects, we are engaged in a common work. It is impossible for those who have to resist the tide of pauperism to act unless they are supported by the Medical Profession generally. It is through the Medical Profession that we must hope to carry out a great many of the needful reforms, and we look to find in your ranks not only men who will heal the body and who will meet those cases of emergency and sickness that arise, but men who will also help the country generally to carry civilising influences into the many nooks and corners where only the doctor can penetrate. We look, therefore, not only to the intellectual efficiency of the medical profession, but also to the general civilizing effects by which medical men, above all others, are able to influence (in common with the clergy) the lower portion of our population (applause). Well, gentlemen, you are come here to study medicine in a place where, above all others, you have an opportunity of seeing how much the medical art is needed. It is here in the east end of London that you have chosen to fix your residence in order to pursue your studies; and you have found here, in the London Hospital, a most effective machinery for accomplishing those objects which you desire to fulfil.

I do not know how far any medical gentlemen here present share those views which have lately been put forward as to the value and the efficiency of hospitals generally. I see that there have been one or two speeches made, and one or two books or reports written, which condemn the system of our large hospitals altogether. Well, I think the best answer to that is, to show the immense good that the hospitals are doing, not only in curing disease, but also in the interests of medical science. What is to become of the medical profession, and what is to become of those practical schools of medicine to which the Dean has so eloquently alluded in his report, if these opportunities for studying disease at the bedside are withdrawn? There is a sentimental grievance sometimes put forward, that it is hard to be an inmate of a hospital—a sentimental grievance is raised by reason of patients being carried away from their own homes, and being put into a large hospital. Well, I think there is never any want of applicants to the hospitals of London. If you can measure these matters by that which I think would be the most practical test—the desire to enter the hospitals—it may happen occasionally that hospitals are not full because they are in want of funds, but never because they are in want of patients (applause). You who go to the bedside in the wards of the London Hospital every day best know how far there are large vacant wards that might be applied to other purposes; you know best whether, with all that which is done by the London Hospital, it would not be possible, if you could add a couple of additional wings to it, to fill them, and whether there would not be a large demand for those additional beds which would be in that way afforded (applause). We have not come yet to that point when every sick patient can be admitted at once to the hospital; I do not believe that the hospital accommodation in the metropolis generally exceeds the demand for admissions. I may be mistaken in that: I know there are cases where there are empty wards; but I have been told that that is on account of the deficiency of funds for keeping up the annual expenses of the hospital, and that there are few medical men who would say that it is from any want of patients to fill them.

Well, gentlemen, you pursue studies upon which it is more difficult for an outsider to speak than, perhaps, any of the studies which are pursued by other classes of professional men. If one of us enter that little room behind here, and look round upon those objects which you view with delight—I won't say the feelings that we experience (laughter)—we cannot follow you in your studies from bedside to bedside; we can indeed appreciate, but only at a distance, the natural scientific delight which you take in a difficult and complicated case. We can feel for you when you even invent a new disease (laughter); but we can only feel for you at a distance; and it is only when you come to the results of that instruction, and that knowledge, which you so laboriously gain, that we really begin to be interested in your skill. We admire that skill; we stand

in daily need of it, though we are not always glad when we come in contact with it (laughter); but, at all events, we recognise the immense value of the services that you render to humanity generally, to every class of society. We value the tact and delicacy, combined with the intellectual powers, that we find in so many medical men; but, as I have said, in the course of the study which you pursue, there is much in which it is difficult for us to sympathise scientifically. But there are many points in which we may envy you: you, at all events, have to deal with facts; you, at all events, feel that if you can only probe deep enough you must come to some substratum of fact at the bottom; you are dealing with positive scientific truth, whereas we, as we sometimes grope about in the field of political economy for economical or political truth, doubt whether there is any bottom or any fact at all. We may have hypotheses as you may have hypotheses, but it is seldom we can by an experiment test them. We cannot experimentalise as you can, and there is no anatomy by which we can trace the secret courses of political disease (applause). It is difficult also for us to receive such aid as you receive in your studies: the aid of practical men, men devoting every hour of their laborious life to the relief of human suffering, yet staying their operations as far as regards their own personal profit; stopping in the course of their practical business to deliver lectures upon scientific and intellectual subjects to those students who are to follow in their steps. Those gentlemen appear to me to render an enormous service to the medical profession who employ themselves in that way. I know no profession that follows the same course in that respect—namely, to pursue at once a practical study and a practical pursuit of their own profession, and at the same time to devote a large portion of their time, and a large portion of that which is as valuable to them as their time—their intellectual power—to the instruction of those students who flock to hear them. (Loud applause.) As to the character of those gentlemen who teach you in this College, it is needless for me to say a word. (Applause.) I see by the expressions of applause by which you have received them, by the hearty manner in which you have expressed your sense of their presence here to-day, that while they have instructed your minds, they have also won your hearts. (Applause.) And while they win your hearts probably they stimulate your emulation; and they make you think of the day when you yourselves will be great names in the medical and surgical profession, for I am sure there is not one amongst you here to-day but thinks that he may attain to that eminence, which in your profession, as in others, is open to merit alone. (Applause.) Why should any of you despair to rival those great names, which are notably of English, but of European reputation—if you continue your studies here with those facilities which are at your hand; and more at your hand, I believe, in some respects, than in any other hospital in London? I am told that you are most prosperous in accidents (laughter), and that you have more accidents to deal with than any other hospital in London. Well, there can be only one compensation for that, which, however one may consider it, must be a deplorable fact; and that compensation you no doubt entertain, namely, that the opportunities which you have for study through the misfortunes of others that are brought here, are likely so to increase your knowledge and your skill that you may be able to be of great use to your fellow-creatures generally. It is absurd to indulge in the sentiment that a school of medicine contains anything that should really jar upon the feelings of any sensible man; because you cannot cure unless you learn, and you cannot learn unless you have the opportunity to acquire the practical knowledge which you gain at the bedside. And I should like to know from those who object to the medical schools, and would thwart your opportunities of learning, if they would like to entrust themselves, their wives, or their children, to practitioners who have not had an opportunity of study in the way which these great hospitals afford? (Applause.)

Well, I would only say one word in conclusion, and that is to allude once more to that connection which exists between those duties which they who have the arrangements of the Poor Law under their charge have to perform and the medical profession. You are the real apostles of health; you have to carry into every corner of the land, and you have opportunities of carrying even into the remotest country districts, proper sanitary ideas. It will depend upon your exertions—it will depend upon the way in which you are able to fulfil the task which you have imposed upon yourselves during those three years which you have spent in this part of Lon-

don—whether the result shall be one which may tend to increase the material prosperity of the country, which may tend to decrease the sufferings of the country, and which may help to remove some of those great causes of ignorance and vice by which we are unfortunately surrounded.

I have been very happy to meet so many eminent members of the medical profession here to-day; I have been most happy to meet so many of those who intend to become eminent members of that profession. (Laughter.) We have heard that there are a great many complaints on the part of medical officers in all the great lines of public life—in the Army, in the Navy, in the Poor-Law Board, and elsewhere—who think that the time has come when their merits should be more substantially rewarded than they are. (Hear, hear, and applause.) Well, no doubt that time will come; and at the same time it is to be borne in mind that it is by the efforts of those who are rising in the profession—it is by the efforts that they make, as I think Dr. Letheby most eloquently said, to furnish themselves not only with professional but with a general, broad education, that they will raise themselves in the estimation of their fellow-citizens, and be able all the better to carry out that great work in which they are engaged. (Loud and continued cheering.)

Mr. CURLING.—On behalf of the teachers of this school, and I am sure I may add on behalf of the students who are here present, allow me to tender to you our cordial thanks for having presided at our meeting this day. We all know the great value of your time; we all know the sacrifices you must make in coming so far east to preside on this occasion; and I may add our thanks are especially due to you for the admirable address to which we have just listened, in which you have eulogised, in kind terms, our pursuits and the nature of our labours. We feel that, holding, as you do, the high and important office of President of the Poor-Law Board, it was very natural that you should allude to the circumstances of a profession which must fall under your notice, for I believe there is no one who is not directly connected with us who can appreciate as you do the services which are and may be rendered by a well-educated profession in all parts of the country.

I think, Sir, that it could hardly have escaped your notice that the majority of those prizes, and the most valuable of them, have been bestowed for clinical and practical instruction; and I quite echo the sentiments you have expressed upon a subject now brought before the profession—namely, "Hospitalism"—for I do not see how without hospitals we should really have the means of instruction. Sir, in this Hospital, with which you are well acquainted—for I think I address you as a Governor of this Hospital—(applause)—our beds are constantly filled with important cases; and no one who desires to become practically acquainted with medicine or surgery can fail to find opportunities within the walls of this Hospital.

I will not at this late hour detain you longer, but will only renew the thanks that we feel we owe you for the honour conferred upon us by your attendance here to-day. (Applause.)

The CHAIRMAN.—Gentlemen, I beg to thank you very cordially for the vote of thanks so kindly proposed, and which you were pleased to receive in the manner you did. I can only repeat the pleasure which I have felt in coming here to-day; and, in conclusion, let me say that if I ever become your subject, I hope it may only be as the subject of your kind remarks. (Laughter and applause.)

Correspondence.

"THE POPULATION QUESTION."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to express my warm thanks to Dr. Waring Curran and Mr. J. H. Levy for their kind assistance in waging war against the inveterate prejudices which, even in our profession, cause many of the most vital points in Hygiene to be so superficially treated. It is too bad, Sir, that Dr. Routh, in the Medical Society, Dr. Kinkead, and a gentleman in Liverpool, should think it necessary in scientific questions to invoke the supernatural. Let me give these gentlemen a quotation from Roman times, "Nullum numen abest, si sit prudentia." Theological arguments now-a-days are

never used except when people are ignorant of the real arguments for their own cause.—Yours, &c.,

C. R. DRYSDALE, M.D., M.R.C.P.

London, July 25.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you have very kindly opened the columns of your Journal for the discussion of the present state of the "social evil," I must trespass a little on your kindness.

Granted that the assertion of Dr. Drysdale in your Journal of 12th May, 1869, "That a woman would of her own accord take to the precarious subsistence of a prostitute in this country for any length of time is an error," is correct, still cases have happened in this country in which women, with incomes that might keep them comfortably during their lives, have gone and prostituted themselves, as I am thoroughly convinced, for the pure love of it. How will Dr. Drysdale account for the fact of several hundreds of our country-women joining the ranks of Mormonism, if it be not a craving desire on their part to follow the life and excitement of prostitutes?

Neither can I agree with Mr. Kinkead in saying "that although poverty existed in Athens the Athenian women did not become prostitutes." The word *ἑσπαι*, which he quotes in favour of his argument, does not, I think, admit of the meaning he puts on it. The manner in which I have seen the word used would plainly indicate that those very *ἑσπαι* were prostitutes; and as the word itself means "guests," not "strange women," as Mr. Kinkead has it, and in order to have a guest I need scarcely say that it is not at all necessary that the person should be a stranger; therefore I would infer that these *ἑσπαι* were guests whom the Athenians invited to join their bed. However, we know from Homer that prostitution existed from the earliest ages, when in his account of the return of Ulysses from Troy he says that he spent a year in the island home of Circe, during which time he cohabited with the goddess.

I think that it is in the education of women, more than anything else, that this morbid desire is fostered. Look at the education of girls of the upper and middle classes in this country, and will you wonder that so many of the beauties of our land have followed the "broad path" to destruction? The very fact of filling their heads with accomplishments and notions which can be of no use to them in after life, except, perhaps, in bringing about their downfall, unsuits their minds for the duties for which the Director of All Good intended them. Go to the wilds of Connemara, or to the prairies of America, and find amongst the females of either of those places, to which those "girls-of-the-period" notions have not as yet penetrated, one prostitute for the ten that are to be found amongst their more enlightened fellow-beings.

As to early marriages getting rid of our prostitutes, I think, from the examples of the French and American systems, that it would be only adding fuel to the fire; so that, considering everything (overcrowding excepted), I think that prostitution would be stamped out only by educating the female in a better manner, by substituting for those very fine ball-room accomplishments an education more calculated to draw forth and improving her intellect; but, above all, by trusting more to her own honour, we shall better accomplish the means we have in view.

Apologising for trespassing so much on your space,

I remain, Sir, your obedient servant,

WILLIAM BULL.

THE SYSTEMS OF ELECTION TO MEDICAL APPOINTMENTS IN THE DUBLIN HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I have read a letter from Dr. Mapother in the MEDICAL PRESS AND CIRCULAR of yesterday, in which he comments on two passages that appear in the letter you did me the favour to publish in your issue of the 14th inst.

With respect to my remarks on the purchase system, he says, "Sir Dominic Corrigan and Mr. Wilmot defend the purchase system as if it were a safeguard against election from personal or political motives." I shall parry this lunge, turning the foil entirely on Sir Dominic, whose mental as well as corporal latitude and longitude so far exceed mine, by the simple negative statement that I never argued in such a direction.

What I *do* say is that I see no reason why a pecuniary value

should not be placed on an hospital appointment, and that to take a purely sentimental view of the matter hardly accords with the utilitarian ideas of the age. Men entering the profession have to pay for lectures, hospital attendance, diplomas, and degrees; and on what rational ground is that which may be viewed as the last link in the chain of qualifications to be given free—that qualification which is in highest repute with the public, and is remunerative in a two-fold sense?

To argue that the purchase-system in any shape ought to be abolished because *all* men of talent cannot pay, is about as reasonable as to argue for the abolition of fees for education, diplomas, and degrees, because all cannot meet these expenses; and thus talent is oppressed and excluded.

I believe if the purchase-system were established on the *proprietary* principle, similar to that adopted in some private medical schools, it would be a security against the so-called "corrupt practices" as far as any human system could prove; it would ensure fair and open transactions, and, in my opinion, meet the monetary capabilities of nearly every aspirant to the office of hospital physician or surgeon.

The second exception taken by Dr. Mapother is to the passage—"No system can create genius, and none retard its progress." This truism has a perfectly logical bearing in the sense in which it is employed in my letter—as a reply to the unfair manner in which Dr. Mapother, and those who joined him in running down the electoral system, dealt with the fact they were obliged to admit—the presence of genius among our hospital physicians and surgeons now and formerly.

The statement that Dublin Hospital physicians and surgeons "have not enlarged the bounds of medical knowledge" is a fair one if Dr. Mapother believes it to be a matter of fact; but the inference to which it leads, viz.: that change to the Parisian or the London system would be alteration for the better, rests on purely gratuitous grounds.

Assuming that the method adopted in Paris and in London works satisfactorily, and fulfils all requirements, we should, before rashly adopting it, pause to ascertain whether all the circumstances, conditions, and necessities of the schools are alike. To drop what we have for the outline of something assumed to be better, is wisdom not unlike that which the fable of the dog and the shadow might, without much ingenuity, be made to illustrate. I quite agree with Dr. Mapother that what I would term *internal progressive promotion* is a sound as well as a just principle. This is the plan we try to carry out in Steevens' Hospital, but it is obvious that too rigid an adherence to it would be to shut the door on free trade, and to exclude fresh and superior talent.

I remain, dear Sir, truly yours,

SAMUEL G. WILMOT.

NOTICES TO CORRESPONDENTS.

IN all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

ON PAIN AT THE HEART, AND IN ITS NEIGHBOURHOOD, by Horace Dobell, M.D.—The first of a short series of papers on this subject is in type, and will appear shortly.

DR. BENNETT, Beechgrove.—The slips shall be sent you in due course.

DR. DAVYS, Swords, shall receive a private note.

DR. EDWARDS CRISP.—The subject to which you refer has been so often commented upon, that we do not consider it necessary to again open the question by printing your letter, especially after the decision of the College to which you submitted your claims some time since, and the still more recent decision of the General Medical Council.

The following Original Communications and Letters are in type, and will appear as soon as space permits:—

The Oxalate of Cerium in Dyspeptic Vomiting, by S. A. Lucas, L.R.C.P.Ed.

Our Analytical Department—Mustard.

Maclister on Reflections of the Peritonæum.

Dr. Kavanagh on Belladonna and Opium.

Dr. Madden on the Use of Forceps.

Dr. Clarke on Tetanus.

COMMUNICATIONS, Enclosures, &c., have been received from Dep. Inspector Gen. Gordon, Fort-mouth; Mr. Black, Edinburgh; Mr. T. Pearce, Holsworthy; Mr. Tichborne, Dublin; Dr. Hawkins; Mr. O'Donovan, Cork; Mr. Daniel, Ramsgate; Mr. Merridith; the Secretary, German Hospital; Dr. Edwards Crisp, Chelsea; Dr. Pantaleoni, Nice; Dr. Drysdale, London; Mr. Walter Rivington, London; Dr. Rumsey, Cheltenham; Dr. Horace Dobell, London; Mr. Hooper; Mr. S. A. Lucas, Liverpool; Dr. Ewing Whittle, Liverpool; Mr. J. Dixon, Leeds; Mr. Bell; Mr. C. Turner; Dr. W. Bull, Nenagh; Dr. S. G. Wilmot, Dublin; Mr. R. McCullum, Shirock; Mr. Gallais; Mr. Ledwich, Dublin; Dr. Oppert, London; Dr. Balthazar Foster, Birmingham; Mr. James Dunne, Dublin; Dr. Frank Hodges, Manchester; Dr. Carpenter; Dr. Browne; Mr. Spencer, Manchester; M. A. B., London; Dr. Davys, Swords, &c., &c.

CASE OF CALCULUS SUCCESSFULLY REMOVED FROM A CAVITY IN THE KIDNEY.

By THOMAS ANNANDALE, F.R.S.E.,
Lecturer on Surgery, Edinburgh.

MR. S—, æt. forty-two, recommended by Dr. James Forrest, of Stirling, came to my house on the 9th of April, 1869, on account of a small fistula in his left loin. The patient gave me the following history of his case:—One year ago he felt, for the first time, a slight pain in his left loin, which occasionally passed down into his abdomen; was never severe, and was usually relieved by rubbing the part with a little laudanum. A few months after the first pain a swelling formed in his left loin, and was opened by Dr. Forrest, with the result of giving exit to several ounces of healthy-looking pus. The wound remained open, and continued to discharge pus, but he suffered no inconvenience, and only had an occasional slight pain in the loin. There never were any urinary symptoms, nor was there at any time any blood, mucus, or pus in his urine. No urine ever passed through the fistula. Three months after the abscess was opened a small calculus, of a triangular shape, passed through the wound, and a few days after Dr. Forrest removed some small gritty particles from the margins of the sinus. One month after this the wound had healed, but required again to be opened, and some more portions of soft calculous matter were extracted. After this the wound contracted very much, and no more calculi passed; but as the sinus still remained open, at the end of several months my advice was asked on the case.

An examination of the patient showed a small sinus,

with a depressed orifice, situated in the left loin, about three inches from the spines of the vertebræ, and immediately below the last rib. There was no swelling or enlargement of the surrounding parts, and no tenderness on pressure. A fine probe, introduced into the sinus, passed down for a depth of three inches, and after a little search its point struck a hard body, which was, without doubt, a stone. Being anxious to ascertain more surely the size and position of the calculus, I proposed to the patient to enlarge the sinus, in order to get my finger introduced. He at once consented, so, having freely incised its superficial margins, I was enabled to get the point of my finger into the sinus, and then, partly by dilatation and partly by cutting, I succeeded in touching the stone, but not until the entire length of my finger had been passed into the wound. The stone lay in a cavity, which appeared to communicate with the sinus by a limited opening, as a considerable portion of the stone was felt to be covered by a soft membranous substance. From the depth of its situation, and from the feel of the surrounding parts, I felt very certain that the stone was lying in a cyst or cavity of the kidney itself. Having proceeded so far, I determined to extract the stone, and accordingly enlarged the wound freely, carefully cutting the deeper portions with a probe-pointed bistoury. A pair of dressing forceps was then introduced, and the stone readily seized, but it seemed to be caught at one or two points, and would not leave its cavity. After one or two attempts, however, I managed to lay hold of the stone obliquely, and to draw it out. The patient, who had complained of great pain in the abdomen while I was touching the deeper part of the wound, bore the operation with great fortitude, and after a few minutes' rest went to a friend's house in a cab. Next day he returned home to Stirling, and, although he was feverish and suffered from pain in the abdomen for a few days, he made a good recovery, and was soon back again to his employment as a photographer. Two days ago (June 1st) I received a letter from my patient to tell me that he had been at his work regularly for the last three weeks, and that the wound was rapidly closing. He has no pain or uneasiness of any kind now.

The stone removed is represented, of natural size, in

FIG. 1.

Fig. 1; it weighed seventy-two grains, was of an elongated shape, and had two branches or processes at one end, and a third process springing from its body. Its length was one and a half inches, and its diameter at the thickest portion was a little more than half an inch. Externally the stone was white in colour, but here and there a brown hue showed itself through the external layer of phosphates. A section, also illustrated in Fig. 1, showed a nucleus the size of a small pea, of a dark brown, almost black colour. Outside this the colour was a lighter brown, and the structure was arranged irregularly and in many lines. Here and there the section showed distinctly an outer thin layer of phosphates. Dr. Arthur Gamgee was good enough to analyze the stone for me, and the following is his report:—

Constituents in 100 parts.

Phosphate of calcium, magnesia, and ammonium ...	14.20
Oxalate of calcium ...	73.35
Organic matter and moisture ...	12.45

100.00

Remarks.—This case is an interesting example of one of the results which occasionally follow the formation and lodgment of a calculus in the kidney. From the composition, shape, and situation of the stone, there is little doubt that it had formed in the kidney, and had given rise to changes in the structure of that organ, such as have been described by Sir B. Brodie,* Prout,† Rayer,‡ Johnson,§ and other authors, and to the abscess and consequent fistula.

Abscesses forming in connection with renal calculi have given rise to fistulous openings in other situations than the loins. Rayer,|| referring to renal fistulæ, says:—"These fistulæ, caused in most cases by the presence of one or more stones in the pelvis or ureter, may open into the cellular tissue external to the peritoneum, into the external lumbar region or near the crural arch, into the colon or duodenum, into the cavity of the peritoneum, or, lastly, into the pleura or lung corresponding to the affected kidney."

When Demonstrator of Anatomy in the University, in the year 1864, my attention was directed to a male subject, about fifty years of age, which had several small fistulous openings in the right loin. These fistulæ passed down in the direction of the right kidney, and small portions of the last two ribs had been absorbed. The right kidney was found to be hollowed into a cyst, and in it lay the calculus figured in illustration 2. I could obtain no

FIG. 2.

history of this case, but feel sure that the stone could have been removed with safety during life.

THE OXALATE OF CERIUM IN DYSPEPTIC VOMITING.

By S. A. LUCAS, L.R.C.P. & S. Edin., Kirkdale, Liverpool.

I FULLY agree with Dr. Curran as to the beneficial effects of the oxalate of cerium in the nausea of pregnancy. I have employed it for vomiting from various causes, with good effects. I have had a case lately of dyspeptic vomiting, where its *tonic* and *sedative* effects were well marked. The patient, a married lady, had been attended by a doctor for two months, suffering from severe vomiting many times in the day. The doctor tried many remedies—bismuth, chlor. potass, lime-water, creasote, hydrocyanic acid, &c.—without giving relief to the patient; he gave the case up. I was sent for, and found the lady suffering from facial neuralgia, as well as the vomiting. I prescribed a liniment to be applied to the face (equal parts of lin. chloroformi and lin. belladonnæ), and put her at once upon—

R Cerii oxal., gr. xxxvj.

Ext. hyos., gr. xxiv.

Div. in pil. xij.; cap. j. ter in die.

For two days afterwards she had no vomiting; on the third day she vomited once, which I believe due to her having eaten potatoes (quite against my prescribed regimen). I made her go out for a short walk every day, and by the end of the week vomiting and neuralgia had disappeared, and her health rapidly returned.

It may be seen from this that the oxalate of cerium in its maximum dose (gr. iij) effected a cure where all other well-known remedies failed; and I hope the profession will give an extended trial to a drug that has not received the attention it merits since its introduction by Professor Simpson.

LITHOTRITY, WITH A NEW LEVER LITHOTRITE.

By PATRICK HERON WATSON, M.D., F.R.S., F.R.C.S.,
Lecturer on Surgery, Surgeon to the Royal Infirmary and Chalmers Hospital.

I WAS requested in the month of March, by Dr. Milne, to see with him Mr. L., æt. 80, who had long suffered from symptoms of calculus and enlarged prostate. I had about a year previously seen this patient, and then operated by lithotripsy upon a calculus fully the size of a large pigeon's egg. The complete relief to the symptoms of urinary retention, from which he had recently begun to suffer, afforded by two crushing operations, led to his refusing to have anything further done at that time, as he was much occupied with family matters. This relief was, however, short-lived, as the old symptoms recurred, and led him at once to accede to Dr. Milne's recommendation, that the operation of lithotripsy should be completed.

On examining the bladder with a converted lithotrite of Messrs. Weiss's pattern, I at once seized a calculus behind the prostate, which measured eight lines upon the scale, and, on adjusting the lever forceps to the shaft of the instrument, proceeded to crush. After opening and closing the handles of the forceps some eight or ten times in rapid succession, I found that nothing farther remained in the bladder to obstruct the free play of the jaws of the lithotrite. I accordingly closed the forceps, and removed the instrument from the bladder. And now, on introducing a catheter with a Clover's washing-bottle attached, I removed a quantity of uric acid detritus, amounting to more than two drachms. The whole procedure, from the introduction of the lithotrite to its removal, occupied less than three minutes. The next day I met this patient in the street perfectly well, and in great glee at the facility with which the crushing had been completed. I have since had an opportunity of examining his bladder, and find no trace of calculous matter in the viscus, though symptoms of irritation due to the enlarged prostate still continue to exist.

I have detailed this case—one among several—in illus-

tration of the employment of a new modification of the crushing power, capable of application to any lithotrite in common use, whereby it can be worked with greatly increased rapidity, and the result attained with equal delicacy of manipulation and even greater power. I was led to invent this lever power at the end of last year, in consequence of a case which occurred in my practice in the autumn. The patient was an exceedingly irritable man, with a uric-acid calculus rather too large for lithotrixy, but who insisted that lithotrixy should be performed, and who could obviously ill bear any frequent repetitions of the procedure, or any long-continued application of the instrument in the ordinary way. The difficulty was in his instance overcome by the employment of chloroform, whereby the stone was crushed at one sitting; but the importance of some more rapid means of applying the crushing power, as suited to such exigencies, forced itself strongly upon my mind.

I accordingly devised the application of leverage by means of moveable forceps, adapted to each blade of the lithotrite, in such wise that the closing of the handles

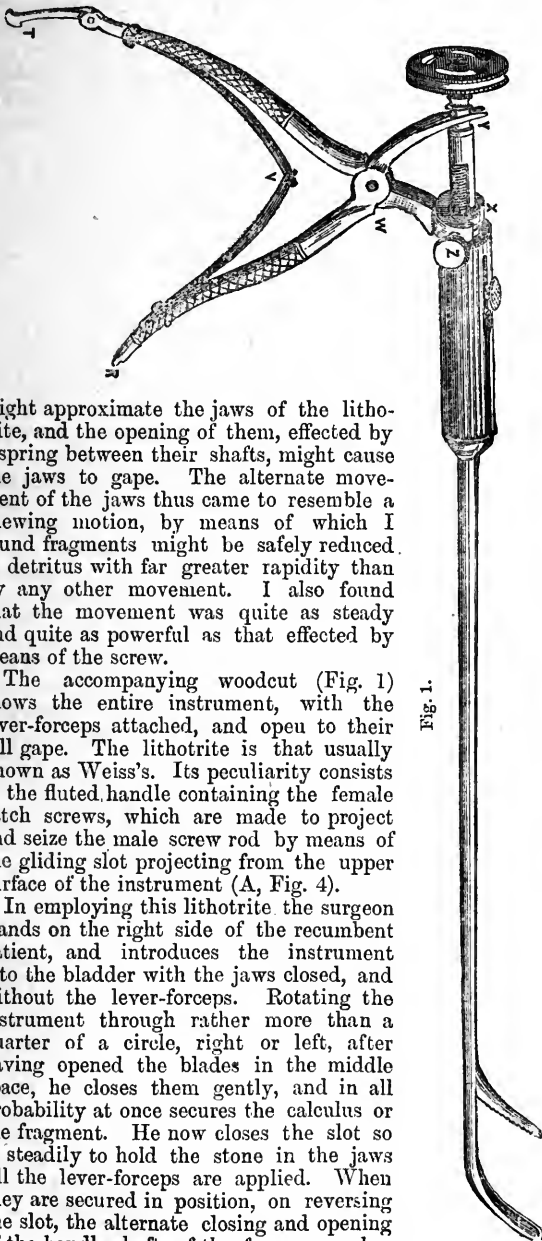

Fig. 1.

might approximate the jaws of the lithotrite, and the opening of them, effected by a spring between their shafts, might cause the jaws to gape. The alternate movement of the jaws thus came to resemble a chewing motion, by means of which I found fragments might be safely reduced to detritus with far greater rapidity than by any other movement. I also found that the movement was quite as steady and quite as powerful as that effected by means of the screw.

The accompanying woodcut (Fig. 1) shows the entire instrument, with the lever-forceps attached, and open to their full gape. The lithotrite is that usually known as Weiss's. Its peculiarity consists in the fluted handle containing the female catch screws, which are made to project and seize the male screw rod by means of the gliding slot projecting from the upper surface of the instrument (A, Fig. 4).

In employing this lithotrite the surgeon stands on the right side of the recumbent patient, and introduces the instrument into the bladder with the jaws closed, and without the lever-forceps. Rotating the instrument through rather more than a quarter of a circle, right or left, after having opened the blades in the middle space, he closes them gently, and in all probability at once secures the calculus or the fragment. He now closes the slot so as steadily to hold the stone in the jaws till the lever-forceps are applied. When they are secured in position, on reversing the slot, the alternate closing and opening of the handle-shafts of the forceps crushes

fragment after fragment. As the larger portions are broken down, the resulting *débris* is easily brought within the grasp of the instrument by a slight rotation of the

Fig. 2.

entire lithotrite. Ultimately nothing but a detritus is left, which can be washed out by the Clover apparatus.

The lever-forceps are shown apart from the lithotrite

Fig. 3.

Fig. 4.

in Fig. 2. One blade terminates in a circular collar X, the other in the fork Y. The collar X encircling the ex-

tremity of the female blade of the lithotrite, is held steady in position by the pinch screw Z, which catches in the groove B C (Figs. 3 and 4), and prevents the slipping of the collar, while, unless screwed up too much, it does not interfere with the rotation of the lithotrite within the collar. The fork Y plays upon the thinned portion of the male blade of the lithotrite at D (Figs. 3 and 4). The elliptical spring which opens the blades is shown at V. A spring-catch is shown open at S T (Fig. 2), by which the blades, when closed, are kept so by the extremity T holding between the fork at R.

Fig. 3 shows the proximal extremity of an ordinary Weiss lithotrite, modified for the application of the lever-forceps, but equally available for use with the screw.

Fig. 4 shows an old-fashioned screw-lithotrite of the early Weiss pattern, modified to suit the forceps, in which the change consists in the removal of the crushing screw, the elongation of the female blade by the grooved projection B C to fit the collar X on the one blade of the forceps, and in a commensurate elongation of the male blade beyond the female blade, with a thin shaft at D, suited to the forked extremity of the other forceps-blade. There is also added a pinch-screw at A, by which the blades may be retained steadily in position after securing the calculus, until the lever-forceps are adjusted. Any form of lithotrite may in this way be modified to suit the application of the lever-forceps, whether it be made upon the model of Charrière, Coxeter, or Sir William Ferguson.

These instruments have all been made or converted for me by Mr. Young, the eminent surgical-instrument maker of this city.

ON UTERINE RHEUMATISM.

By J. WARING CURRAN, L.K., Q.C.P.I., L.R.C.S.I., &c.

ALTHOUGH it is not unfrequent for the fibrous structure of the uterus to become implicated more or less during the course of an attack of acute rheumatism, yet I believe the fact of the disease manifesting itself by first seizing on that organ and its appendices unusual, whilst it is calculated to mislead what the actual nature of the complaint is, until the more ordinary and more striking symptoms are developed. The recital of the three following cases, will not, I conceive, be uninteresting nor unimportant:—

CASE 1.—On the 20th of January, 1867, I was requested to visit a married woman, the mother of four children, about thirty-seven years of age. She had been exposed to cold and wet, and had experienced a severe rigor on the morning of my first visit. Her chief complaint was of intense and continued pain above the pubis. The bowels were freely relieved by a domestic aperient. There was no vomiting. The urine was sufficient in quantity, but in character highly coloured and cloudy. She had menstruated naturally a fortnight previously, and the history of her life, physically, was that she had never required medical attendance except during the parturient state. Upon examining the region corresponding to the seat of pain, I discovered no superficial tenderness, no abnormal condition of the part, but upon employing firm pressure with the ends of the fingers, she cried out against the punishment inflicted. I was in this way enabled to encircle, so to speak, the uterus and determine that the mischief existed there and was confined to that organ. However, although the tongue was coated with a creamy fur, and the pulse was quick, and the surface of the body dry and hot, I considered the symptoms would yield to an active saline, and that the pain would be relieved by the local application of a liniment consisting of aconite, belladonna, and chloroform, applied to the affected region on lint and covered in order to prevent evaporation, with gutta percha membrane. On the day following, I found little alteration in the general symptoms. She expressed receiving temporary relief from

the liniment, but was in truth unable to turn in bed, or move the body, from the severity of the pain which movement produced. I made then a still more minute and careful examination, the result of which was, that I arrived at the conclusion, that the case before me was one of acute inflammation of the uterus. The pressing and distressing nature of the symptoms justified the opinion. Upon this, I applied leeches, and prescribed calomel and opium in pill, and a diaphoretic mixture. At my evening visit, I further directed that extract of belladonna, diluted with glycerine, should be smeared over the part; this covered by silk paper, and a bran poultice to be applied external to all. The subsequent day the inflammatory fever still ran high and unsubdued, but the uterine pain was less acute, and the left shoulder joint became implicated; towards evening, the nature of the case had thoroughly revealed itself, other joints were affected, and a case of acute rheumatism lay unmasked before me. From the moment the *materies morbi* of the rheumatism dispersed itself over the system, the uterine pain lessened. The case ran an ordinary course under an alkaline treatment, the heart escaped, and the woman fully recovered, and is now well in health, and has been free from any subsequent return of the rheumatism.

CASE 2.—A. G. was an arthritic subject, and had been on two occasions under treatment for sub-acute attacks of rheumatism. She was forty-six years of age, and the catamenia had ceased three years before. She sought advice for severe pain of two days' duration, in the right iliac region extending to the spine behind. There was also pain of a rheumatic character complained of in the calf of the right leg. I directed an anodyne liniment to be applied, and a saline aperient to be administered. The next visit I paid her I found the mischief to have concentrated itself upon the body of the uterus, whilst the pains elsewhere were in abeyance; towards the evening of that day the symptoms became so aggravated that I was compelled to direct the application of leeches. The day following, the swelling of the joints, and the acid perspiration, and urine charged with lithates, clearly indicated the nature of the case to be dealt with. And here I may avail myself of the opportunity of stating that in the treatment of rheumatism I have given an extensive and fair trial to the application of small blisters to the affected joints, and that the result has been disappointment where they are trumpeted to be successful. My application to a joint or joints so affected is the extract of belladonna rubbed down in glycerine, smeared over the surface of the joint, covered with silk paper, and to the outside of this gutta percha pile wrung out of warm water frequently renewed. The relief which I have invariably observed resulting is very great indeed, rendering the exhibition of opiates and other sedatives unnecessary, which otherwise would only retard the action of the eliminatives requisite in such cases. Again, the blistering adds little to the comfort of the patient, if it does not increase the misery of his condition; whilst in no instance have I ever observed it hasten recovery.

CASE 3.—In the autumn of last year a young unmarried female of robust health and appearance waited upon me for advice respecting severe headache, and intense pain at the lower part of the abdomen, both of which commenced simultaneously the preceding day. She considered that she had caught cold during the menstrual period which had just terminated, as the catamenia had abruptly stopped. The other secretions were normal, but the pulse was full and quick, and there were the other usual symptoms of general feverishness about her. I recommended that she should have a warm hip-bath, prescribed some aperient pills with a diaphoretic mixture, and advised upon her return home to retire to bed. In the middle of the night I was sent for, but having an obstetric engagement I was unable to go, and she was seen at my request by another medical gentleman, who, from the nature of the symptoms which presented themselves to him, gave it as his opinion that she was suffering from meningitis, and that the uterine affection was of a secondary nature and

of secondary importance. The patient was seen by us together early the next day, when we materially differed respecting the precise nature of the case, or the accuracy of the diagnosis to be arrived at. The similarity of the symptoms to those mentioned in Case 1, and the impression which that case made upon me, dictated the hardness of announcing rheumatism. In four-and-twenty hours this disease thoroughly developed itself in one of the hands, which became all at once puffed and painful. Very soon several of the joints joined issue, and notwithstanding the powerful remedial efforts to combat the disease, we had a tedious and complicated case to deal with.

The pericardium and heart became participators in the disease, but what seemed curious that during our attendance, which extended over a period of some six or seven weeks, that the disease commencing in the uterus, appeared to adhere to that organ throughout, and although at times not so severe, was the last portion of the system to depart from.

Of course, I have observed many cases wherein during the course of an attack of rheumatic fever the uterus was affected, and in which the pain became so distressing that the exhibition of tincture of aconite was essential; but I have nowhere witnessed such thorough cases of uterine rheumatism as in the three whose histories I have just recorded.

Last year in the columns of the MEDICAL PRESS AND CIRCULAR, in a paper on *Ovarian Neuralgia*, which has been extensively reprinted, I advocated the great value and efficacy of aconite as a therapeutic agent in that complaint. I believe now, and experience justifies the opinion, that in rheumatic complications of the uterus or its appendices, aconite is equally important as a remedial agent of great virtue and reliable power.

A CURIOUS EXIT FOR A PIN, WHICH WAS SWALLOWED FOURTEEN MONTHS PREVIOUSLY—RECOVERY.

By FRANCIS McEVoy, L.K.Q.C.P., L.M., M.R.C.S. Eng., Balbriggan.

AN extern patient was brought to the dispensary by his mother, who informed me that her son was about thirteen years of age, that he lately complained very much of a pain in his stomach which made him cry, and it usually attacked him when he bent forward with his chest against the table, as in writing and learning his lessons. At such times he suffered from a shooting pain, as if something suddenly darted into his stomach. His appetite was excellent, he slept well, enjoyed good health in every other respect, was cheerful and lively, but latterly seemed unwilling to play with other boys as he used to, and said that he was afraid of their hurting his stomach. At first his mother was inclined to attribute it to worms, as he had passed some at various times, and had even thrown up one or two by mouth. Then to his having taken a dislike to school and study; that idea was not tenable, as he evinced the greatest anxiety about learning. I examined him carefully, and questioned him closely as to feeling and health; he complained of but the one thing, a pricking sensation when he bent forward against anything. Upon the closest examination I could detect nothing to account for the feeling he had. I therefore looked upon it as one of those obstinate cases of worms which are sometimes met with, and will baffle the most skilful to cause their expulsion. I gave him some pulv. sautoninè, with various other vermifuges, and although he expelled half-a-dozen large worms, yet he obtained no alleviation of the symptoms complained of.

Having tried various remedies without effect, I recommended his mother to try further advice, or get him into

hospital, which she did. In about six months afterwards she came to me again,—having in the meantime brought him to various medical men, and having had him in two hospitals without deriving any benefit; but, on the contrary, he evidently became worse,—to request that I would go see her son, as he was getting a lump like a boil just over his stomach where he formerly had the pain, which was gone since the lump had made its appearance. I was very much surprised to see him reduced in so short a time from a fine, plump, healthy looking boy, to a mere skeleton—so emaciated had he become that I did not know him.

On examining the lump it proved to be a small abscess fully developed. His mother informed me that about three weeks ago, he began to complain of his trousers hurting him, and that on examination, she found a fulness and a circumscribed hardness, which day by day became red and soft, and so sore that he was obliged to take to his bed altogether for the last fortnight.

I at once opened it, and, whilst doing so, became aware that the point of the lancet came in contact with a hard substance. I immediately, before the matter was all discharged, passed a bulb-pointed silver probe into the abscess, and struck something that grated against the instrument. By working it backward and forward, I managed to get the point towards the opening, seized it with a forceps, and extracted a pin the cause of all his ills. About fourteen months previously he swallowed a pin, which he recollected the moment he saw it. He recovered rapidly, and in a very few weeks resumed his usual health, strength, and spirits. He has since emigrated to America. I was one day paying him a visit, and asked him how he happened to swallow the pin. He told me that one day coming from school, he picked up that very pin and put it into his mouth. Another boy tripped up his heels, and he got rather a severe fall. He could not at the time say whether it fell out of his mouth or not, but did not recollect having swallowed it.

EXIT OF A PIN SWALLOWED FIVE YEARS BEFORE.

By ALEXANDER CHAIN, L.R.C.P., L.R.C.S. Edin., Liverpool.

ON the 4th of June I was requested by Mr. W. to see his daughter, a fine healthy-looking girl, aged fourteen years. On inquiry I ascertained that for some eight or ten days previous to my visit she had suffered considerable pain in consequence of the formation of an abscess on her back, situated a little above and internal to the inferior angle of the right scapula. When I saw her the pain had almost subsided; fluctuation was readily detected, but there was no appearance of pointing. A sharp-pointed bistoury was pushed into the softest part, and about an ounce of healthy pus escaped.

On sponging the part before applying a poultice, I discovered a foreign body lying obliquely across the aperture. I seized it with a pair of forceps, and, to my astonishment, extracted a pin. The mother, who was standing close by, on seeing this instantly exclaimed, "Doctor, that's the pin she swallowed five years ago." This is another instance of a foreign body, without producing the slightest inconvenience, remaining in the system for years before making its way to the surface.

GOITRE CRETINISM.

M. GARRIGON, consulting physician at the Mineral Springs of Aix, asserts that certain endemics are due to the existence of magnesia, and more especially to the silicate of that earth, in the soil, which modifies all organisms, both vegetable and animal. His doctrine is based upon extensive observations made in the districts of the Pyrenees where such maladies are endemic, and are coincident with such geological constitution.

Our Analytical Department.

M U S T A R D.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

THE importance of mustard, both as a condiment and as a medicine, can hardly be underrated. As regards the first, it is perhaps second to none. It is a stimulant to the digestive organs in small doses, and upon this property rests its great popularity from a dietetic point of view. In larger doses it acts as an emetic, which latter, combined with its vesicating properties, constitutes its main medicinal applications.

The mustard of commerce is generally made from both the white mustard seeds, *sinapis alba*, and the black, *sinapis nigra*.

These seeds, however, differ considerably in appearance and chemical composition.

The white mustard seeds are much the larger of the two, and generally average one-tenth of a grain in weight when dry. They consist of yellowish, nearly round, white seeds; they are inodorous, and even when mixed with water are not so pungent as the black mustard seed. White mustard yields about 36 per cent. of a yellow fixed oil, nearly inodorous, which is not solidified in the cold. Its flour is yellow, but not so dark as that obtained from the black. One hundred parts of the dry seeds give 4.45 of ash, having the following composition:—

Potash, 25.78; soda, .33; lime, 19.1; magnesia, 5.9; ferric oxide, .39; sulphuric anhydride, 2.19; silica, 44.9; trace of chlorine and phosphoric acid. One hundred parts of the air-dried seeds were found to contain 8.5 parts of moisture, and 1.21 parts of sulphur.

A solution of perchloride of iron strikes a red colour, with a watery infusion of white mustard seeds. Myrosine, a compound formed in the seeds, is an emulsion-like substance contained in the seeds of the black and white mustard, particularly in the latter, and is one of the most important ingredients.

Myronic acid exists largely in the black seed, but not in the white; it is present in the form of a potassium salt. When these two substances react upon each other in the presence of water, a peculiar change takes place, resulting in the production of sulpho-cyanate of allyl, or the volatile oil of mustard.

This oil, to which mustard owes its peculiar properties, will be described further on. It is not present in the mustard until it has been subjected to the action of water, and cannot be procured under any circumstances from the white seed alone. The object of the manufacturer using a mixture of the two seeds, and the special directions for mixing mustard, which are frequently appended to the canisters, is, therefore, self-evident. These directions are very essential, but are frequently needlessly elaborated. Any good mustard may be properly made, and its virtues fully developed, by mixing in the ordinary manner with lukewarm water, which must never exceed 80° Fahr. It should be made rather stiff, and at the expiration of twenty minutes a little vinegar and a very small quantity of salt added. Unless the mustard be of a

very low class, this will generally keep remarkably well, and the volatile oil will be generated as far as the decomposition can proceed. Mustards that are sold ready made should contain nothing but the above ingredients.

Some years ago mustard was principally raised at Durham, and thus the term "Durham mustard." In Bailey's "Survey of Durham" he says that—"Mustard was not known in its present form at our tables until 1720. The seed had previously been merely pounded in a mortar. At the period referred to, it occurred to a woman of the name of Clements, residing in Durham, to grind the seeds in a mill, and to treat the meal in the same way that flour is treated. Her mustard was, in consequence, very superior, and being approved by George I., speedily came into general use. Mrs. Clements kept her secret for a considerable time, and acquired a considerable fortune." In Bengal and other eastern countries mustard is extensively cultivated for its fixed oil, as rape is in Europe.

Dr. Pereira gives the following as being the process for manufacturing mustard:—The seeds of white and black mustards are first crushed between rollers, and then pounded in mortars. The pounded seeds are then sifted. The residue in the sieve is called dressings or siftings, what passes through is impure flour of mustard. The latter, by a second sifting, yields pure flour of mustard and a second quantity of dressings. By pressure the dressings yield a fixed oil, which is used for mixing in with rape and other oils.

Most of the best manufacturers, however, now remove part of the fixed oil before dressing. There seems to be six qualities, or brands, known in the trade: "seconds," "fine," "superfine," "double superfine," "brown," and "genuine."

Mustard is said to be extensively adulterated with turmeric, salt, Cayenne pepper, radish seed, pea flour, rape seed, pepper, chrome yellow, wheat flour, &c.

At the time of Dr. Hassall's report on mustard, there seems to have been, as now, four to six qualities made. He says, of the four most generally supplied qualities:—

"The first is called 'seconds'; it is usually of a bright yellow colour, but is thickly studded over with numerous black or reddish-black points; these are fragments of the husk of black mustard seed.

"The next quality is termed fine; it also presents a considerable number of black specks, but fewer than in the former case.

"The third quality is called 'superfine'; it is spotted to a much less extent, although minute specks are still visible.

"The fourth, or last quality, is the double superfine; in this the eye can scarcely detect husk at all, although with the microscope a little may still be discovered.

"The several qualities are vended to the public by a wholesale and retail establishment in the City at the following rates:—'Seconds,' 5d.; 'fine,' 8d.; 'superfine,' 11d.; 'double superfine,' 1s. 2d."

The prices now seem to be in the first-class shops as follows, about:—Seconds, 6d; fine, 1s.; superfine, 1s. 4d.; double superfine, 1s. 8d.; genuine, 2s. The first prices were in 1855. Almost every manufacturer also seems to send out a fifth article marked "genuine," which is not mentioned in Dr. Hassall's Report, and was evidently unknown at the Parliamentary inquiry in 1855. This article seems to have been introduced within the last few years. It will be seen, further on, that the qualities do not only specify a different amount of dressings, but *different phases of adulteration*. We will take these adulterations *seriatim*.

Mineral adulterations and the ash.—We have not met with a case of mustard adulterated with mineral colours, such as chrome yellow; but it is necessary to carefully estimate the ash, as it will be seen, by our analyses further on, that an increase in the ash is indicative of a pretty general, but nevertheless an abominable adulteration. We believe we are the first to have recorded the extensive use of this sophistication, and it has evidently so far escaped observation. The colour and general characteristics of the ash should be observed. It should be nearly white, and should not become discoloured when treated with sulphide of ammonium. If the quantity exceeds 5 per cent., the ash must be analysed, as the mustard is probably adulterated.

Adulteration with wheat and other flours.—Wheat flour seems to be almost the universal adulterant of mustard, and is used most extensively for this purpose. We have not met with cases of pea or other flours, but they can all be easily determined in mustard by the aid of the microscope, which distinguishes between the different starch granules appertaining to the different flours. Mustard is perfectly free from starch.

FIG. 9.—Wheat Starch, magnified 200 diameters.

The presence of a small quantity of flour might be very easily missed on applying the iodine test.* Mustard seems to have a greater attraction for the iodine than the starch granules, and forms a deep yellow compound, which might disguise the presence of a small quantity of starch.

Turmeric.—Turmeric, or some other colouring matter, must be used wherever the mustard is adulterated with flour. Accum, in his "Treatise on the Adulteration of Food" ("Death in the Pot"), says:—"It has often been stated that a fine yellow colour is given to mustard by means of turmeric. We doubt the truth of this assertion. The presence of the minutest quantity may be detected by adding to the mustard a few drops of a solution of potash, or any other alkali which changes the bright yellow colour to a brown or deep orange tint." It is evident that either turmeric was not used at the time this book was published (1820), or that Mr. Accum did not possess the facilities for analysis which we have at present. Turmeric is largely used in mustard in connection with wheaten flour. Turmeric contains a peculiar starch, but not in large quan-

ties; whilst the turmeric is itself used in such small proportions in mustard, that the microscopic appearance is of no value for determining this point. It is, however, easy of detection. We at first thought that the examination of an alcoholic solution of the mustard, by means of a prism, might have afforded an easy mode of detection for this substance. When light is analyzed by a prism, after passing through tincture of turmeric, the more refrangible or blue end of the spectrum is absorbed or cut off to what is known as the solar line F at the blue end. On the addition of ammonia, the absorption or cutting off increases through the green up to the line E. However, as mustard yellow obscures this end of the spectrum also, though not to the same extent, it is evident that it is not applicable to the detection of a minimum of turmeric in a maximum of the mustard yellow. There is, however, one most characteristic point in connection with turmeric, which is, that the alcohol solution exhibits a remarkable green fluorescence, which is not exhibited by mustard yellow. The phenomenon is even more striking than the reaction with ammonia, which latter substance strikes a reddish brown colour, restored by acids. This test may be used as confirmatory. The following are Prof. Stokes' directions as regards viewing or detecting fluorescence in substances:—"A glass containing water, and blackened internally at the bottom, is placed at a window, and the solution to be examined as to its fluorescent tint is placed in a test tube which is held vertically in the water, the top slightly inclined from the window, and the observer regarding the fluorescent light from above, looking outside the test tube." The smallest quantity of turmeric imparts to alcohol a green, and strongly marked fluorescence is seen almost more strikingly in very slightly tinged solutions.

Peppers.—The peppers are extensively used to adulterate mustard, particularly capsicums. They may be detected by the microscope, but we depend upon the following method:—"A tincture, made by treating with strong alcohol the suspected mustard, is evaporated to dryness on a watch glass, using a water bath for this purpose. The presence of peppers can then be at once recognised by their smell or taste. The residue from genuine mustard leaves no burning sensation in the mouth, similar to that felt from the peppers. As regards the adulteration with pepper, Dr. Hassall, in his Report, remarks—"Adulteration with pod or capsicum pepper. It is stated that pod pepper is commonly present in mustard. We have diligently searched for it, but have not hitherto detected it in any sample."—Vide "Food and its Adulterations," by Arthur Hill Hassall, M.D. London, 1855. (p. 128.)

It will be seen from our report that mustards are frequently adulterated with capsicums; and whilst upon this subject we must remark that we think such a report as the above-mentioned one is of very little practical value. Of the forty-two samples examined by Dr. Hassall, only about seventeen of them had any brand or name of maker or vendor. Of what practical use is it to know that "24th sample, purchased in Oxford street, and labelled 'Finest Durham Mustard,' contained a large proportion of wheaten flour, was coloured with turmeric, and that there was little lusk visible?" Such paragraphs can only afford a little local interest for the people of Oxford street, with its 552 houses, to guess where sample 24 was bought at.

We have found pepper present in samples from four manufacturers. It is frequently found in Irish mustards

* The iodine test consists in adding a few drops of a solution of iodine in iodide of potassium to the suspected mustard. Starch, if present in any quantity, should instantly strike a blue colour in the cold.

which have a celebrity. The red particles of capsicum pods can frequently be seen in mustards by the naked eye, or by a very moderate magnifying glass. Black peppers cannot be well detected in this manner without magnifying about 150 diameters, as the cuticle of the mustard, or "hulls," as they are termed, cannot be distinguished therefrom by the eye.

(To be continued.)

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

HEREDITARY SYPHILIS.

By Mr. MORGAN, F.R.C.S.I., Professor of Anatomy
R.C.S.I., Surgeon to the Hospital.

Syphilitic Hydrocephalus.

AMONGST the numerous phases of hereditary taint, hydrocephalus has been enumerated as an occasional one, and is acknowledged by many accurate observers.

Thus Haase gives the case of a woman who was delivered on three consecutive occasions of a dead child at the eighth month. She then produced a hydrocephalic child, with spots on the skin, which died when six months old, and had two more pregnancies of living though tainted children.

Lancereaux mentions the case of a woman who, having produced several hydrocephalic children, on inquiry it was found that her husband had formerly contracted syphilis.

De Meric in Lettsomian lecture 1858, remarks the syphilitic influence in producing hydrocephalus, and also the frequency of the upturning and rotatory motion of the eyes in these cases.

The indubitable existence of syphilitic taint, the occurrence of hydrocephalus in a puny offspring, accompanied by the rotatory motion of the eyes, and insomnia, were well marked in the following case:—

M. A. G., aged twenty-eight, Ward 12, has had five children: the first, six years ago, which died when some months old; the second, four and a half years since, which died at eight months (these were not affected with disease, which the mother had not, as yet, suffered from); the third, three and a half years since, when she gave birth to twins, who both died of constitutional syphilis, which the mother had contracted, and had shown an eruption during the pregnancy.

The fourth time she gave birth to a boy, the subject of this case.

This child, æt. twelve months, was admitted June, 1869, suffering from hydrocephalus and general debility. The enlargement of the head showed itself in May last. Since then the child gradually declined; the most marked symptom it now had being the upturning and rotatory motion of the eyes, which scarcely ever ceased for many days previous to its death; and as sleeplessness was also constant, these symptoms were the more noticeable. The child gradually sank, and a careful examination was made.

On opening the head there was but little external fluid, but the ventricles were distended with a clear serum to about two ounces. The abdominal viscera were healthy, excepting the left lobe of the liver, which presented a slight eminence of a yellowish colour, but hardly consistent enough to constitute a gummatous tumour. The kidneys, &c., were normal. The heart had on its front a very large white spot equalling a sixpence in size. The right lung was infiltrated with dense gummatous or semitubercular matter enclosing an isolated abscess, the body generally

being much wasted, but presenting no external marks of disease.

Case of Fatty Degeneration of the Placenta.

The frequency of premature expulsion of the foetus in cases of syphilitic infection has been the source of some speculation when the foetus has arrived at such a period as to be otherwise viable. The occurrence of fatty degeneration of the placenta, so well described by Dr. Barnes as an efficient cause of defective nutrition to the foetus, is well illustrated by the following case just now under my notice:—

C. S., Ward No. 11, aged thirty-two, admitted June, 1869, has already given birth to three children at nine months, both dead born: she has been diseased twice; once about three years ago with discharge and bubo, and had a rash four years ago; has been suffering from nocturnal pains; is thin and worn, but not affected by any phthisical influence, and is pregnant, between the seventh and eighth months; the motions of the child have not been perceived. For eight or ten days, and for three days previous to her confinement, she has been complaining of weight and uneasiness. On July 26th, after a labour of about three hours' duration, she was delivered of a dead and slightly decomposed foetus, the placenta, which followed directly the delivery, was very soft, pale, and rent on the slightest handling, so much so that it was difficult to keep it intact. It appeared to have suffered complete degeneration, greasing tissue paper by contact, and the tufts becoming more distinctly vascular by washing with ether.

The foetus presented no internal evidence of disease, all the organs being healthy and well formed, corresponding to the eighth month.

A NEW METHOD FOR SECURING DIVIDED VESSELS.

Frederick D. Lente, M.D., of Cold Spring, N. Y. (*Am. Journal Med. Sciences*), recommends the silver wire for securing divided arteries, and makes the application as follows: Cut off a length of silver wire, say three inches, less will do, however, for small arteries; give it a sharp bend in the middle, then one or two twists as near the bend as possible. This forms the ligature. Secure the twisted end of the ligature in a pair of spring or catch forceps. Draw out the vessel to be ligated, or, if a small one, the tissue in which it is, with a tenaculum or forceps, in the usual manner; let an assistant apply the ligature against the vessel at the point where the two legs diverge from the twist; then the surgeon takes hold of the two ends and gives as sharp a twist on the vessel as possible, and then secures the hold by two or three half turns. The silver wire is so soft and pliable that but very few turns are necessary to prevent slipping. These ligatures may be applied with great facility, after a little practice. He uses the ordinary suture wire for the smaller arteries, and No. 26 for large arteries. Having twisted the wire, the end is cut off with ordinary scissors, within two or three turns of the artery; the other end, if not too long, may be left, as two sharp ends to the ligature would be avoided. This leaves a very minute quantity of metal around each vessel, and after a dozen such ligatures have been applied, it becomes somewhat difficult, in the course of half an hour, to find one of them, except by searching carefully. They soon imbed themselves in the tissues, and disappear from sight. An important object, in substituting silver wire for silk in ligating arteries divided in operations, is to secure a better chance for "union by first intention." The danger of death from an open, suppurating wound, with its constant liability to erysipelas, pyæmia, exhaustive discharges, and a long train of evils, is avoided.

ALCOHOL IN LARGE DOSES IN POISONING BY MUSHROOMS.

M. POULET, in a communication to the Académie des Sciences, affirms that alcohol in large doses is a veritable antidote to the poisonous mushrooms of the genus *amanite*; and he believes it equally valuable in the poisoning by other species of mushroom. The author adds that ebullition in water, impregnated with salt or vinegar, is insufficient to render the poisonous varieties inoffensive, and that the *agaric bulbeux* in particular always retains a great portion of its toxic principle. —*Gaz. Hebdom.* 1864, No. 41.

WEDNESDAY, AUGUST 4, 1869.

THE STUDENTS' PRELIMINARY.

LAST week was held at the Royal College of Surgeons in Ireland the first preliminary examination since the appointment of a majority of new members on the Board of Examiners.

Some remarks from us may, therefore, be appropriate on the occasion, chiefly as a guide to the studies of future candidates for the examination.

In some respects this examination is the most important that the candidate for admission into the medical profession will be called upon to undergo. As regards himself personally, rather than his patients, and his future well-being in and enjoyment of his profession, we may safely affirm this. If he gets through at his final examination without sufficient study, he may perchance find opportunity for further study afterwards; but if at the preliminary examination he is allowed to pass when he ought not, it is merely launching him upon a profession for which he has proved his incapacity, it is allowing seed to be sown where want of soil has been demonstrated; indeed, as the preliminary examination is at present constituted, we might say that it is permitting a dwarf to devote himself for life to work that requires the strength of a giant. Nothing can result from it but dissatisfaction to himself as well as to his patients; nothing but a life-long regret that he did not adopt some other path in life, that of the army, the navy, or merchant marine, that of a clerk, that of a farmer,—anything rather than a profession in which brains are the essential thing, and for which brains are deficient. For the preliminary examination is intended to test two things: first, that the candidate possesses the brains necessary for the practice of the profession with satisfaction to himself and safety to others; secondly, that he has so far employed his brains as to render the very

peculiar language of the profession intelligible to him, so that what he may hear in the hospital wards and the lecture rooms, and what he may read in medical works during his four years of professional study shall not be absolutely an unknown tongue to him.

We regard the scientific portion of the examination as specially directed to the former of these two objects, and the classical to the latter.

We understand that the new members of the Board agreed together that this occasion, as being their first examination, they would mark with special leniency, and that in point of fact, several of the candidates who declined two or even three passages taken at random from the beginning, middle, and end of the author they selected, and who proved themselves unable even to read the words of the language, were nevertheless credited with a 2, the marks ranging from 0 to 10. We much doubt if candidates on future occasions can reckon on the same leniency being shown; and we may take this opportunity of reminding them, that by a recent rule of the Council they are not permitted to select a passage for themselves from the author they bring up, nor to decline the passage offered them by the examiner.

We would strongly recommend candidates to pay particular attention to reading the classical languages with accuracy; this will be a valuable training in that accuracy of study which is so essential to the successful pursuit of medicine. The reading of many of the candidates on the recent occasion was found to be extremely bad, and it is highly probably that on future occasions separate and equal marks may be given for reading, translation, and grammar, the final mark in the subject being the average of these three. As regards translation, we may warn candidates that to rattle on with the English version learnt off by rote will certainly not be permitted, but that they will undoubtedly be required to give the English of each individual word; and this we recommend them carefully to prepare, so that a lamentable ignorance of the most frequently recurring words may not be exhibited, for the risk of rejection would be serious.

Some little attention ought also to be given to grammar, so that the parts of speech should not be confounded, and that acquaintance should be shown with the more marked tenses, that σ should be recognised as the sign of the 1st Future, $\sigma\alpha$ of the 1st Aorist, and a reduplication of the Perfect.

It is undoubtedly the intention of the examiners to make that superficial and expeditious preparation commonly called “cramming” impossible, and so to test the acquirements of the candidates as to ensure that, on the one hand, every man shall pass who has average brains, and who shall have devoted a reasonable proportion of time during his schoolboy years to preparation, and that, on the other hand, the man devoid of brains, or he who, in sudden disgust at the shop or the farm, has determined to “have a try” at medicine, and has crammed six months for that purpose, shall be without fail rejected; and such a discrimination it is possible to make with a single author brought up as easily as with a dozen; but the student who wishes to know his business would do well to read widely in the Latin and Greek classics, and not confine himself to the single author he purposes to bring up.

It is highly probable that on future occasions an absolute standard will be fixed, to which every candidate must attain in every subject, probably four, or thereabouts:

but if a candidate should answer very well in other subjects, so as to obtain a sum total above the average fixed for passing, which on the recent occasion was 40 per cent., it is possible the examiners might seek permission from the Council to reject him only in the one or two subjects in which he might have failed, and to permit him to devote his whole attention to those subjects for the next examination.

Finally we would counsel rejected candidates not to indulge in unmeasured regrets at their rejection, but to rest assured that, unless indeed their own diligence be at fault, which it is for them to remedy, they had in their ignorance selected a profession for which they were wholly incompetent, and that the passing pain of a rejection at the preliminary has saved them a lifetime of unavailing regret, when too late to embark on any other pursuit.

THE WATER QUESTION.

WANTED, a Member of Parliament who is not afraid of statistics being thrown at him, to ask whether the Government approve of *ex parte* statements being circulated at the public expense?

All the world is aware that the Report of the Commission on Water Supply has given much dissatisfaction to a number of persons who had, perhaps hastily, embraced a particular theory. As these gentlemen have the ear of the Registrar-General, their views have been circulated by him for a long time, but have lately been combated by those equally, and, perhaps, more competent to judge. At any rate the Commission has unequivocally condemned them. But what do we now find—a settlement? By no means. The condemned theorists are ready to run a tilt with the Commission, and seem not particularly scrupulous as to the mode in which they will wage war.

Some of the papers have accordingly published articles which it would be affectation to call inspired, for they have the unmistakable style of certain individuals who are committed to the hypothesis, and who apparently have little to do but to endeavour to propagate their views. This we do not object to. Papers which choose to accept articles on scientific points that commit them to any theory have as much right to do so as those who volunteer such aid have to present the editors with the articles. We hope the theorists will not forsake the editors at a critical moment. But while we do not condemn such volunteer "labours of love," while we have never objected to our non-scientific contemporaries indulging their friends with parading their theories, we do take exception to the Reports of the Registrar-General being made a vehicle for controversy.

The last Weekly Return of this official is accompanied by a supplement of sixteen pages, devoted entirely to controverting the conclusions of the Commission. It has often been remarked that the Registrar-General's Returns are a collection of facts. Are we to suffer them to inflict upon us an unlimited amount of theory? We have not the least objection to any one pulling the Report of the Commission to pieces. If they can, let them show that Report to be all nonsense. But let this be done in the proper place, and certainly an official publication like this is not the one.

That some of the officials of the Registrar-General's department may feel that their opinions have received a

rude shock by the Report of the Commission, we can easily believe; but it is not likely that the public will think it right for persons whose evidence was heard and sifted by the Commission, to be allowed to make an attack on their opponents through the columns of the Weekly Returns of Births and Deaths in London and the Large Towns.

We are not now about to enter on the controversy that has commenced. We have avoided the error of those of our contemporaries which have adopted one hypothesis, given full publicity to that, and avoided mentioning anything that would not exactly confirm the views to which they were committed. Such a course may be very well for non-scientific newspapers. Such a *role* has been played by a journal or two that professes to be scientific. But to true men of science nothing can be more contemptible than the conduct in question. Even the men who think with them will not hold the editors of such papers in very high respect. They know their inspiration—their pretension—their ignorance. They are content to wait for the evidence on which the Commission is founded. They will peruse that evidence with care, and form their own opinions independently of anonymous contributions to the public press. Above all, such men—and their opinion alone is of value—are least likely to be influenced by the indecorous haste with which the Registrar-General's columns have been made the medium of *ex parte* statements.

SCOTLAND.

A TESTIMONIAL is to be raised to Mr. Syme by his former pupils. It is thought a marble bust and a Surgical Scholarship would be appropriate. Dr. Murchison, of London, will be glad to receive names.

THE Minutes officially communicated by the Edinburgh University Court confirm our statement as to lady doctors.

Notes on Current Topics.

Contagious Diseases.

THE Report of the Committee of the House of Commons, just out, agrees in many particulars with that of the Upper House.

The investigation has not extended to the whole civil population; has, in fact, only inquired as to the operation of the Act that is now being tried, and to the localities where it is most felt to be wanted. Some recommendations for extending the area of the Act are made, and it is proposed that young girls who become prostitutes with the connivance of their parents should be removed from their influence to industrial schools. The Report recommends a new Committee to be appointed next Session, to take into consideration the propriety of extending the Act to the civil population.

Medical Council.

WE have endeavoured to convey to our readers—not only a just estimate of the doings of this body—but of the need there is for something to be done to reform it.

We have further quoted the opinions of our contemporaries to prove that this question is becoming one on which the public will insist on something being done. We have now the satisfaction to quote from the *Times*, which on Friday last, in its report of the Leeds Meeting, thus brought the reform of the Medical Council before its readers:—

“It is, perhaps, not so well known to the public as it deserves to be that the control of medical education and of the registration of qualified practitioners is vested, or is supposed to be vested, in a Council composed of 24 members, of whom 18 are elected by the various corporations and Universities that give the medical licences, and the remaining 6 are nominated by the Crown. The elected members are elected, not by the graduates or licentiates, but by the small governing Boards of the bodies they are supposed to represent, and hence they are by many thought to be chosen with reference to the private interests or rivalries of corporations rather than with reference to the wants of the profession as a whole, or to its legitimate aspirations after a higher standard of education and of efficiency. At present these various corporations, such as the several Colleges of Physicians and of Surgeons, are practically rivals in the business of conferring medical qualifications upon the candidates for them, and derive considerable revenues from the fees that those candidates pay. It follows that such rivals can hardly escape being suspected of practising some of the ordinary devices of competition; or of attracting pupils to their respective portals by straining a point or two in the way of laxity of examination. The Council, so largely composed of their nominees, has, therefore, to a great extent, lost the confidence of the profession; and there is a very general desire among enlightened medical reformers to see it in some way remodelled. It is felt that many of its present members are not in a position to initiate any beneficial change in medical education; because they are, in fact, the mouth-pieces of the very bodies for which reform is urgently required. It is, therefore, sought on all hands that there should be some sufficient direct representation of the profession on the Council; but opinions are divided as to the way in which this direct representation could be most easily and most efficiently obtained. On this point, however, it is more than probable that any scheme devised by the profession would undergo considerable modification in Parliament before it was embodied in an amended medical Act, and it is therefore wholly superfluous to discuss the comparative advantages of rival schemes. It is, however, by no means superfluous to call public attention to the broad outlines of the question. The efficiency of medical education and the nature of the test that are applied to candidates for licences to practise are matters that concern everybody, and when the great bulk of the more active and intelligent members of the profession loudly complain that in these respects there is much of which they disapprove, they are entitled to be heard with attention, and to be assisted in the realisation of any desires that commend themselves to the common sense of intelligent persons. Now, without affirming that the complaints against the present examining bodies are well founded, and without supposing it to be entirely true that the best efforts of medical teachers are seriously hindered by the ease with which idle students may enter the profession through certain very widely-open portals, we still do not hesitate to affirm that the persons chosen as representatives by small committees of elderly men are, on the whole, more likely to be bent upon resisting change than to be energetic in promoting improvement. Without condemning existing examinations, we do not hesitate to affirm that a competition among examining Boards for the fees of students is essentially unsound in principle, and that it need occasion no surprise to hear that such a competition has led to disastrous results in practice. The British Medical Association seems, therefore, to be engaged in a work of public utility when it declares, as it has now declared repeatedly, that the Medical Council ought to be composed of men who distinctly represent the profession independently of vested interests; and that this Council, or some other competent authority, should have power to fix, and from time to time to revise, some standard of medical education and examination that should be regarded as a *minimum* qualification for practice, that should be the only door of entrance to the profession, and to which all other qualifications and degrees should be but appendages, to be sought or to be done without according to the tastes, the line of work, or the

honourable ambition of the practitioner. From the adoption of these two essential principles it would follow—first, that the public would be better protected than now against possible ignorance or incompetence; secondly, that the old corporations would enter upon a new race and a different kind of competition, striving to make their respective degrees esteemed by reason of their value; and, thirdly, that the supervising Council would be continually stimulated to efficiency by the pressure of their constituents upon its members. It is probable that the whole question will be made the subject of legislation in an early Session of Parliament, and it is to be hoped when that time comes that it may receive the careful consideration that is due to its great practical bearing upon the health, and even upon the lives, of the community.”

Royal College of Physicians, London.

THIS College has taken the greatest step towards Medical Reform yet accomplished—no other than a step towards the one faculty system. It has shown that it has power to license in surgery, as well as medicine, and the Poor-Law Board henceforth recognizes the licence as a double qualification.

If we are to have general practitioners affiliated to the College of Physicians at all, this is the greatest benefit that could accrue. It will rouse the Conservative College of Surgeons to a sense of the rights of its members—so long ignored.

We only hope the College of Physicians will stand firm by its rights and not be entrapped into a trial of anything but this one faculty system.

The only thing to consider is, what shall become of the *Members* who have not passed that chrysalis state to the full-blown *Fellowship*?

Really something ought to be done for this hard-wedged middle-class. Are the Fellows so “up in a balloon” as not to see this?

Decision at the Poor-Law Board.

THE St. Pancras Guardians have at last done something. They have induced the Poor-Law Board virtually to supersede them—an example we hope to see followed on every similar occasion. It will be remembered that on the Board reinstating the Master after a careful inquiry, the Guardians further suspended him, thus setting the decision at naught. The Board at once put in force the 200th section of the Act, by prohibiting the St. Pancras Guardians from suspending any officer whatever until April 17, 1870, the date when the new Guardians to be elected by the ratepayers will take their seat. We congratulate Mr. Goschen on the vigour he has infused into the Poor-Law Board.

The Metropolitan Underground Railway.

THE energetic manager of this line, in connection with the engineers, have been devising from time to time modes for ventilating the tunnels and stations. Still the air is impure. During the next few days another, and apparently a very simple process, for rendering the air sweet and pure, will be tried at one of the worst ventilated stations of the line. The invention is by a member of our profession, Dr. M'Grigor Croft, of St. John's Wood. The method has met the approval of highly scientific men, apart from and connected with the railway. We look forward to the result, which is stated must be satisfactory, with anxiety, as the importance of fresh air in this railway cannot be too much appreciated. Dr. Croft superintends his own system of ventilation.

The Heat in India.

THE *Pioneer* says it is with the greatest difficulty the railway officials can get out-door work done in consequence of the excessive heat. The shunting and making-up of trains, especially in large stations like Allahabad and Cawnpore, is a serious matter at present. The driver of a goods train, which left Allahabad at three o'clock p.m. last Monday (the 21st), died near the Sirsoul station on Tuesday morning of heat apoplexy. The man was in perfect health when he left Allahabad.

Appointments of India Medical Officers on Furlough.

THE Governor-General of India, in Council, having considered the views expressed by the several local Governments and administrations, is of opinion "that a medical officer in charge of a civil station should, when proceeding on furlough, retain a lien on some similar appointment, i.e., the charge of a civil station of the same class, or some other civil charge of equal emoluments. He should not, as a general rule, have any claim to reappointment to the same station."

In accordance with an opinion expressed in the Military Department of the Government of India, the Governor-General, in Council, has resolved that in cases in which the furlough allowance of a medical officer in civil employ, calculated according to Rule V. of the Military Leave Rules on the average salary drawn by him for three years prior to his proceeding on furlough, does not equal half of his unemployed pay, the difference shall be added to the furlough allowance.

Native Aspirants to the Medical Service.

THE native element (says the *Indian Daily News*) is pushing itself forward into the services, and his battle for place will yet be waged. Baboo Bepun Behary Dutt, who joined the Royal College of Surgeons and Physicians, Edinburgh, in May, 1867, and passed his first professional examination in medicine of double qualification in January, 1868, has this year passed his final examination held on the 7th May last. There were fourteen candidates, and only three passed; he is one of the successful three, and now wishes to become a military surgeon. He intends joining the Army Medical School or Royal Victoria Hospital at Netley, where he will attend a course of practical instruction. The course lasts for four months, and then he hopes to be one of Her Majesty's first Hindoo covenanted military surgeons that is not a convert, like Dr. S. G. Chuckerbutty and others, but a Hindoo.

A Physical Diagnosis.

THE *Boston Medical and Surgical Journal* publishes the following very amusing report of an investigation of disease by a quack:—

“ _____, Jan. 31d 1869.

“ Miss _____. At the request of Mrs. _____ We have taken your hair to examine, as she could not attend to it by sickness in her family, her Husband and Daughter were both taken sick, and we were call there to attend them and she gave us the hair, and requested us to examine it. We find on examination of your hair that there is a good deal of humor in the head and round the secretion of the throat, there is humor on the nerve of the ear that conveys the sound from the Drum of the ear to the brain causes those noises, and all other bad feelings in your head,

you have catarrhal trouble, but that is not occasion of Phelm in the stomach, there is canker all about the throat Lungs Stomach, the coating on the Liver is very thick, it is very inactive, the Kidneys do not do there office as they ought to, the oil of the blood is watery, the midriff dose not assist the Lunges, the bowels are very inactive state at times, We think the Povity of the blood causes very many pains and aches about you, your blood has commenced to change and you are all riled up, it turns the Middle of march, We would not advise you to take any more of the snuff at Present, We will Leave the head as it is and doctor the blood which will be the surest way to assist you. We would rectermend the following things for a syrup,

“This delicious composition breaks off abruptly here, the patient having torn off the prescription of ‘things for a syrup,’ at the time she received the letter. Mr. Editor, isn't it almost time to emigrate ?

“ W. W. M.”

The Outbreak of Cholera at Nusseerabad.

WE (*Poona Observer*) are exceedingly glad to learn, from telegraphic reports furnished to the Adjutant General, that the cholera at Nusseerabad is disappearing. From the 11th to the 18th inst. no fresh admissions to hospital were recorded. The following table, dating from the 7th of June to the 11th, shows the extent to which the disease raged:—

Date.	Admission.	Deaths.
June 7th.....	4	0
„ 8th.....	5	3
„ 9th.....	5	3
„ 10th.....	0	1
Total	14	7

It will thus be seen that rumour considerably over-estimated the virulence with which the scourge was raging.

Quarterly Return of Births and Deaths in the City of Dublin and Suburbs.

In the Dublin Registration District the number of births registered during the thirteen weeks ending Saturday, July 3, 1869, amounted to 2,030, being equal to an annual ratio of 1 in 39, or 26 in every 1,000 of the population. There were registered in London during the same period an annual ratio of 1 in 30, in Glasgow 1 in 23, and in Edinburgh 1 in 26. The number of deaths amounted to 1,816, affording an annual ratio of 1 in 43, or 23 in every 1,000 of the population. The number of deaths registered in London during the same period was equal to an annual ratio of 1 in 45, in Glasgow the number was equal to 1 in 27, and in Edinburgh an annual ratio of 1 in 30. The disease which proved most fatal during the quarter was bronchitis, which contributed 277 deaths, or 1 in 6.6 of the total deaths. In the corresponding period of the year 1868 the deaths from bronchitis numbered 220. Fifty-seven deaths resulted from pneumonia or inflammation of the lungs. In the corresponding quarter of last year 48 deaths were ascribed to pneumonia. Seventy-five deaths resulted from fever, viz., 19 from typhus, 38 from typhoid or enteric, and 18 from simple continued fever. Scarlet fever caused 99 deaths, showing a decrease of 54 as compared with the preceding quarter. Measles was the cause of 19 deaths. Sixteen deaths were caused by croup. No death from whooping-cough was registered during the quarter. In the corresponding quarter of last year 73 deaths from this disease were registered. Two hundred and sixty-two deaths were referred to phthisis, or pulmo-

nary consumption. Mesenteric disease was the cause of 25 deaths, and hydrocephalus or water on the brain of 41. Eighty-five deaths were ascribed to heart disease, and 8 to aneurism. To liver disease 43 deaths were ascribed. Thirteen deaths were referred to kidney disease unspecified, and 16 to nephria or Bright's disease. Fifty-eight violent deaths were registered, of these 42 were accidental, 5 homicidal, and 9 suicidal, and in two instances the specific violence was not stated.

Health of Dublin.

IN the Dublin Registration District the births during the week ending July 24th amounted to 185. The average number in the corresponding week of the years 1864 to '68 inclusive, was 171. The deaths were 99. The average number in the corresponding week of the previous five years was 112. Four deaths were caused by fever, viz., 1 by typhus, 1 by typhoid, and 2 by simple continual fever. Scarlet fever proved fatal in 5 instances, and measles in 3. Five deaths were ascribed to diarrhœa. Five children were carried off by convulsions. Ten deaths resulted from bronchitis, and 5 from pneumonia, or inflammation of the lungs. Two deaths were referred to apoplexy, and 3 to paralysis. A man aged 20 years died in the North Dublin Union Workhouse, assigned cause of death "solis ictus or sun stroke;" duration of illness 4 or 5 days. Three deaths were caused by heart disease, and a like number by liver disease. Phthisis or pulmonary consumption was the cause of 13 deaths, and water on the brain of 4. Two accidental deaths were registered, viz., a boy aged 14 years, "fracture of skull caused by machinery in motion" (inquest); and a man aged 37 years, "fracture of skull, the result of a fall from a window" (inquest).

THE Director-General of the Naval Medical Department has completed his inspection of Haslar Hospital.

THE Queen has given £100 to University College Hospital. The Marquis of Westminster has presented £200 to the same charity.

THE British Association for the Advancement of Science will hold their annual meeting at Exeter on the 18th proximo. Professor Stokes is president elect.

DIARRHŒA has begun in London. From 102 deaths in the previous week, the Registrar-General reports a rise to 253 last week.

THE *Pioneer* understands, "on good authority," that the Medical Officers of Her Majesty's Indian Army are preparing a memorial for transmission to Government regarding the unsatisfactory state of the Medical Retiring Fund.

A CATTLE-PLAGUE is prevailing in the districts of Balasore and Kanti. The following are the symptoms, as described by a native Bengali paper:—"The body becomes feverish; a substance resembling phlegm exudes from the mouth and nose; the ears become insensible to sound; food is refused, and death supervenes. In some instances the body is covered with ulcerated swellings. The local name of the disease is *go-bushuntu*."

A NEW wing to the Hospital for Women was opened last week by the Princess Teck.

DR. STEPHENSON, of Mile End, died lately, a victim to devotion to his duties, in which he contracted fever.

WE regret to announce the death of Dr. C. D. Mergs, of Jefferson Medical College. He died in Pennsylvania, June 22nd, and in him America loses her first obstetrician.

THE Rev. M. J. Berkeley is convinced that the so-called cholera fungi have no existence, and seems likely to put an end to the question. His article in the *Monthly Microscopical* should be read by the credulous.

THE Jubbulpore paper has been informed that of thirty-five Europeans employed on No. 17 contract on the G. I. P. line, no less than seventeen have died during the past hot season.

DR. THORNE THORNE, who was lately appointed to the Fever Hospital, has been given a Demonstratorship of Microscopic Anatomy at St. Bartholomew's Hospital. He has therefore resigned the Royal Hospital for Diseases of the Chest, at which there is consequently a vacancy.

WE understand that Dr. Alexander MacAlister of Dublin has resigned his office of Surgeon to the Adelaide Hospital, Dublin, in consequence of his having been elected to the Professorship of Zoology in the University of Dublin. Mr. MacAlister has distinguished a very early scientific career by unremitting zeal and much originality of thought in the investigation of subjects in comparative anatomy and natural history. His selection to the chair which he will in future occupy is a just and popular recognition of his devotion to the sciences which it will be, henceforth, his duty to teach.

THE MEDICAL MEETING AT LEEDS.

THE British Medical Association has had its annual meeting, and has been handsomely entertained by the good people of Leeds, the town selected for this year's assembly. The proceedings opened on Tuesday, the 27th ult., when Dr. Aeland resigned the presidential chair to Dr. Charles Chadwick, the Senior Physician to the Leeds Infirmary, who has been elected President for the present year.

DR. CHADWICK, who was received with loud applause, then delivered the following Annual Address:—

GENTLEMEN,—I offer you a cordial welcome to this our annual gathering, and I do this the more readily because I give it in the name of the entire profession of this town. In many instances, being of a partial character, the welcome has lost its heartiness, through the easily recognised absence of some of the notabilities of the place giving a degree of coldness to the otherwise cordial reception. We are fortunately unanimous in our desire to do honour to our brethren, who will be, for a few days, our visitors; and, in honouring them, to recognise the high value and importance of the Association to which we all belong. The exceptions to this singular unanimity are so singularly few, and, where existing, in nearly every instance, on sufficient ground, that I feel it an imperative duty to give the fact an emphatic prominence. There has been no party or individual jealousy; and whether we fail or succeed in the object we have ardently desired, all have frankly co-operated to deserve success. In the name, then, of the unanimous profession of Leeds, I bid you welcome. (Applause.) Among

the many objects which these meetings contemplate, none is more important than the estimate and record of our professional advancement; and in no department has a forward movement been, of late years, more distinctly illustrated than in the construction, arrangement, and working of our hospitals. You are all aware of the fact that in this town has recently been completed a new General Hospital, which with some others of recent construction in different parts of the country, constitute an era, a marked and distinct step in advance in this important matter. In the selection, therefore, of the subject for my presidential address, I seem to have no choice; and I propose to offer you a simple narrative of what we have accomplished in connection with our hospital arrangements. Contrary to a somewhat prevalent (fashionable I had almost said) opinion, we have erected our hospital within the precincts of the town. In regard to the site itself, as a suburban one, it could not, under the circumstances, have been more favourable. It has a gentle southerly declension, the exact nature of which will be particularised when I speak of the building itself. It is situated to the windward of the town, at the gorge of a valley running directly east and west, and in its elevation is exposed to a free current of air blowing directly from the neighbouring moorlands, continuous with the hills whereon we find the most salubrious atmosphere of our district. At times its force may be somewhat energetic, but there is thus secured a purity few town atmospheres can boast. I do not venture to dispute that, other things being equal, so far as purity is concerned, a country site would have advantages over this. But this is really the only valid argument in favour of a country over a town location, except perhaps the cheapness of land, whilst the preference we have given to the latter is supported by a multitude of advantages which far outweigh the admitted potency of the other. In arriving at this conclusion we were mainly influenced by the central position of the site in the district whence the patients are derived, and its immediate proximity to a railway station affording facile communication with every part of those large hives of industry which principally supply the Infirmary, with patients. The convenience of the honorary medical officers, and the opportunities here afforded for professional instruction, were not forgotten. In reference to the first-named advantage, I think you will unanimously discard the insinuations to be found in writings deservedly exercising a great influence on the public mind, that the degree of talent brought to bear on hospital treatment is of little moment compared with other requisites, such as country site, perfect ventilation, and efficient nursing. To each of these I would give their due importance, but never at the expense of underrating our constant, self-denying, and invaluable services. Fortunately, so long as these services are rendered gratuitously, the staff of any given hospital will continue to embrace a large proportion of the medical and surgical talent of the town or district in which it is placed. Remove the hospitals to the country, and the whole plan of management must be changed; honorary hospital attendance must cease; the fully occupied, and therefore it is fair to presume most able officers, will no longer attend. Adopt the alternative which has been proposed, and pay them for their services and the remuneration necessarily inadequate, the same result will follow. A lower grade of professional talent will supply the place, to the detriment alike of the public and the profession; strongly I deprecate this possibility. Much of the honour and influence we have is due to the long-continued services we have rendered in these institutions, and therefore I dwell upon it with confidence, in combating a general resort to country sites. I would adopt, as will afterwards be seen, all the appliances which modern philanthropy has devised and a wise liberality has given, whereby the difficulties of town hospitals may be lessened. But we have now a very momentous question to encounter—a question which, unless answered satisfactorily in the negative, involves a serious dilemma—Are these palatial hospitals, as they have somewhat derisively been designated, a mistake? Are they as detrimental to successful practice as, relying upon authoritative statement, would at first sight appear? The objection to them is not new. Brocklesby, the friend of Johnson and Boswell, the successor of Sir John Pringle, clearly entertained the notion that, at least for military purposes, in tents or hastily-constructed huts, more satisfactory results could be effected for the sick and wounded, than by the same practice carried on in regular or temporary hospitals. The idea has long been entertained in respect to civil hospitals, and has again been recently revived by a distinguished fellow-associate. His name alone gives an importance and authority to any opinions he may adopt—opinions

it would be rash enough for us to disregard, except after the most satisfactory investigation. I do not mean to assert that we are prepared to negative his conclusions, but I do believe there is sufficient to warrant a suspension of our judgment, and to prevent the public adopting any extreme idea until it is proved to rest upon incontrovertible data. Sir Jas. Simpson has arrived at the utter condemnation of large hospitals, relying upon the military experience already referred to, and upon the recent results of hospital treatment during the Crimean war. He also attaches great importance to the difference between the mortality in civil hospitals, particularly as regards amputations, and the same operations when performed in the homes of patients, however humble or circumscribed they may be; or in those village hospitals which are springing up so abundantly throughout the land. After giving a quotation from Sir James Simpson's letter on the subject, which appeared in the *Scotsman* on the 12th January last, the President proceeded:—This is a question which demands from our Association a very careful and candid investigation, and we must remember that the country looks to us for an impartial verdict, be the consequences of that verdict what they may. We will adopt Sir James's statement as to the diminished mortality in cottages and cottage hospitals. We will not just now insinuate that there may exist some serious fallacy in the way these statistics have been taken, nor will we at present quote some singular exceptions to these statements we have met with in our inquiries. We know that the mortality has been very large; we will admit that there seems to be made out a very strong case in this amputation test, and that the attempted explanation through a more careful analysis of these cases, as to their primary and secondary character, has failed. We do not believe, however, that the question can be decided in this manner, and we must first inquire whether the improved principles upon which hospitals are now constructed may not be the turning point of the whole question. We use, therefore, as an important argument, the admitted superiority of hospital results during the earlier years of their history, as established by Sir James Simpson. We accept the statement of the late Mr. Liston without question, believing it to be true, and we regard as historical Monroe's record of the first hundred amputations performed in the Edinburgh Hospital, with the mortality of one in twelve; and we ask, with considerable confidence, if these results, and better than these, may not be anticipated with the larger cubic space in which the hospital patient now breathes, and the wider superficial area upon which he lies? Will not, likewise, the more perfect ventilation, the non-impregnated—often less absorbent—materials employed in the construction of ward walls and floors, contribute to the same results? And upon this we will venture to assert that this large mortality, as it does not occur in the earlier years of the hospital, cannot be an inherent element of hospital practice, and that the happier results, as exhibited in the experience of Mr. Liston and in the statements of Monroe, will no longer be confined to the first few years of the hospital's history, but become a continuous and characteristic result of their statistics. To maintain the uncontaminated condition of the new hospital in perpetuity seems to be the great desideratum; and may we not look to the great improvements in surgical science—for I still concern myself with the amputation test—to contribute to this end, as well as those other improvements in constitution and management to which I have already referred? And then will be brought about a gradual assimilation of hospital results with those obtained in private practice, in whatever grade in life. I have referred to the improvements in surgical science, and amongst many others to which I might refer, the antiseptic treatment of Mr. Lister, of Glasgow, occurs to me as the most apposite. I would have it remembered that the large proportion of open suppurating wounds in a surgical ward may be a powerful aid to the contamination of its atmosphere, and this necessarily the more potent the older and more deteriorated the ward itself has become. Now, the treatment of Mr. Lister, as I understand it, entirely does away with this fertile source of mischief, and he assures me "that some of the most unhealthy wards in the kingdom have become, through its adoption, all that could be desired, being quite free from pyæmia, erysipelas, and hospital gangrene." The system of using wards in rotation will, if strictly carried out, prove a means powerfully preventative of contamination; by this I mean the plan of having at least one ward always vacant, and, not only the ward itself, but its furniture likewise. I have preferred in the above remarks confining myself to the surgical illustration, simply because it has

been so strongly relied upon; but I might have found in reference to other cases a stronger support of our present form of hospital. I might have referred to the smaller mortality—the safer and more convenient management of many medical cases than can be effected in their own homes. Let us simply refer to scarlatina, typhus and typhoid fevers, rheumatism, &c. These do not suffer, but the contrary, from hospital treatment. But time will not allow me further to prosecute the illustration; and if I have thus made out a case for the suspension of our condemnation of the present form of hospital, then, indeed, my arguments will have additional force from their greater convenience and their less costly management. In the cottage hospitals, spread over a larger extent of surface, which could only be effected at a distance from a town, every species of attendance must be more difficult and expensive, supervision would be impossible, the labours of the resident and honorary staff largely augmented, and hospital instruction almost impracticable. It is, I think, beyond dispute that as hospitals have hitherto been constructed and managed, they do in process of time undergo contamination. This arises mainly from continuous imperfect ventilation—the concentration of morbid elements, gaseous and solid, the latter contained in the vapour exhalations from the lungs and cutaneous surface of diseased subjects. These have over and over again been demonstrated, the solid animal matter being separated from its solvent, the watery vapour, when condensed, upon the windows and walls of the ill-ventilated wards. Little attention having been paid to the selection of non-absorbent materials for construction, the results cannot be wondered at. Another fertile source of contamination is the imperfectly-constructed floors and the improper methods employed in cleaning them. The Leeds New Infirmary and the Herbert Hospital at Woolwich are the first complete hospitals built in England on the pavilion principle. I do not put it forward as an exact and perfect adoption of the pavilion plan, but it so very nearly approaches to it that, for all essential purposes, it may fairly be so denominated. To have made it perfect, however, would have involved us in many difficulties—the increase of our already expensive site, and the sacrifice of much facility of working. The Bordeaux Hospital, besides being the first, is also the most exact specimen of the kind with which I am acquainted; but one of its defects is the small space between its pavilions, though I have not been able to find an exact measurement. Another defect is the extreme height of the wards—namely, thirty feet. The Leeds Hospital is arranged on the normal plan of a cloistered quadrangle in the centre, from which the pavilions branch out north and south. The width of the ground only permits three pavilions on either side of the central court, and administrative requirements other than the special objects of the Infirmary necessitated the use of one of the southern spaces—so that the hospital really consists of five pavilions. The site slopes some twenty-five or thirty feet from north to south in the direction of the length of the pavilions. This introduces a peculiar and unusual feature—that the most convenient point of entrance is not at the end of the central court, but at the lowest end of the ground where the central southern pavilion would have been erected but for the valid reasons already furnished. Hence the public entrance is placed in what would in the usual arrangement be the flank of the building, and on a level one storey lower than that of the ground floor of the pavilions—so that whilst that floor at the northern end of the site is on the natural ground level it runs out at the opposite end to a height some twenty or more feet above the level of the grand entrance. There is, as usual, a gateway leading into the central court, but this becomes a secondary entrance—all comers to the hospital using that in the centre of the flank just referred to, and proceeding thence by a bold corridor to the great staircase, which rises to the flank of the central court, and thence by the upper cloister conducts to the pavilion floor. It will be seen that this arrangement gives to one half of the building an extra ground storey of full height. This is appropriated mainly to the several purposes of administration. It may be named in passing that the Board rooms and other offices for the use of the governing body are placed near and over the main entrance. Remembering the situation of the out-patient department, the kitchens, &c., it becomes at once apparent that those only who are concerned in the treatment of the sick need go up to the hospital floor, whilst those who have to do with the administration proper need only visit those parts which are completely severed from the Infirmary. The result of this is that on reaching the hospital level the entire space is devoted to the actual uses of the patients, and

no culinary or other administrative work is transacted on this floor. The centre space occupied by the cloistered quadrangle has been covered over by a light and elegant glass and iron roof, which may form a winter garden. This covered area presents a striking feature of the institution, and may efficiently subserve its important purposes. The strictest care has been taken to secure its proper ventilation, so that it cannot form a machine for the transmission of contaminated hospital atmosphere from one pavilion to another. This winter garden, though not an original portion of the design, now forms one of its most attractive characteristics, promising, besides its intrinsic beauty, to become, if successfully managed, an important adjunct in the treatment of the sick. Some have feared that the lofty glass roof would seriously interfere with that due circulation of air around the exterior of the pavilion which forms a distinctive element of the system. Any one who will enquire into this objection on visiting the upper parts of the Infirmary will find that no extra corners or angles have been erected, and bearing in mind the normal currents of air in this elevated position, will be satisfied that no detriment of this kind need be apprehended. My own conviction is, that if any effect is produced by it, the influence is beneficial rather than otherwise for the objects supposed to be interfered with. At one end of this is an entrance gateway, before referred to, and on either sides are the dwellings of the superintendent and nurses of her staff. This presents another important feature of the hospital deserving comment, in which our architect has successfully complied with his instructions, and again illustrates the excellence of the design in the complete isolation of its different departments. I now refer to the very desirable separation, in all similar institutions, of the nurses from the other domestics of the administrative department. This arrangement, I believe, will materially facilitate the satisfactory working of the institution. Our nursing staff at present consists of one lady superintendent, sixteen head nurses, ten probationers, four scrubbers—one occasional. Six wards only are as yet opened, containing beds for 180 patients, of which sixty are medical cases and 120 surgical. At the end of the winter garden and opposite to the nurses' house, is a very handsome chapel, in perfect keeping with the general architectural features of the hospital, and liberally furnished and decorated by several generous benefactors of the institution. From the northern flank of this central quadrangle branch out three pavilions, and from the southern flank two, the central space in the last-named side being occupied by the grand staircase and central corridor leading from the south entrance. Behind the top of this staircase and over a portion of the central corridor is the operating theatre, upon which both as to its lighting and general arrangement our surgeons have expended much careful consideration. The pavilions are of two storeys, and one ward only occupies the entire length of the pavilion. We have placed one ward over another, though quite prepared to admit that hospitals of one storey possess many advantages. The non-transmission of hospital atmosphere from one storey to another is the main advantage derived from these erections. With the perfect ventilation we have secured, the objection is reduced to its minimum of force, and various reasons, economical and otherwise, might be added in justification of this selection. In fever hospitals particularly, single storeys have still stronger claims for adoption, and I don't hesitate to affirm that in the neighbouring town of Bradford there is now in course of erection the most perfectly designed hospital of this class in the country. The exact measurement of our wards is as follows:—

	Beds.	High. feet.	Long. feet.	Wide. feet.	Space.	Area.
Upper North.....	32	19	122	27-6	1,992	104
Lower North.....	32	16-6	122	27-6	1,875	104
Upper South.....	28	19	112	27-6	2,055	108
Lower South.....	28	16-6	112	27-6	1,782	108

In our ward construction another prominent feature of our plan is manifest—large wards are preferred to numerous small ones, mainly on the following grounds:—1st. They are more easily ventilated. 2nd. They are more effectually and more economically administered. In these, when windows are opposite, not too widely separated, and capable of being sufficiently opened, the most perfect ventilation may be kept up without any undue disturbance of the atmosphere of the ward by currents or draughts. I should not recommend a wider space between the windows than thirty feet, and even a somewhat smaller measurement may be allowed, as in our own hospital, with advantage, if, as it is desirable, the head of the bed

stands a short distance from the wall, and with the ordinary length of bed ample breadth of central passage is secured to permit other requisite ward furniture to be arranged conveniently. The height of the ward is a more important element than at first sight appears. From sixteen to twenty feet may be mentioned as appropriate to wards of 120 to 130 feet in length, and a breadth of about twenty feet. This affords an ample floor area for each bed. In the second place, large wards are more efficiently and economically administered. The question is altogether distinct from the force required to nurse a ward, large or small. It will not be disputed that whoever is responsible for the management of a given number of patients, must have constantly under her eye the entire area of her work. This cannot be the case if 28, 32, or 40 patients are distributed in four or six wards; and allowing for waste of force in simply passing from one room to another, more subordinates will be needed when the patients are thus placed in several wards. It is pretty well understood that one head nurse may properly carry out the care and oversight of from thirty to forty patients, and wards of this size, and on this account amongst others, should be generally preferred. And though I would not assert that small wards can altogether be dispensed with, their use should, for efficient management, be reduced to a minimum. A light screen placed around the bed will in many instances secure all the needful quiet and privacy required, and thus answers most of the intentions of the small ward. If these arguments are admitted to have the force which much thought and arguing have given them in my mind, I need not refer to the difficulties which will embarrass profession treating in small wards, and other minor objections which might be raised against their general adoption. I am aware, however, that some few cases, such as *delirium tremens*, and certain cases of disease of the eye, imperatively demand separation, and no well-arranged hospital should be entirely without smaller wards. The large amount of window space in this and in all modern structures for the same purpose affords a striking and advantageous contrast with those of earlier construction. There are eight windows on each side of the southern, and seven upon each side of the northern wards, and one large window at the end of each. These are all divided by mullions, and so contrived as to admit of opening and shutting, as the need for ventilation demands. The side ones reach from about three feet above the floor, to within one or less than one foot from the ceiling. In addition to these freely-opening windows there are ventilators in the ceiling communicating by transverse with the open air, on either side of the pavilion, and likewise grates, capable of being closed at will, upon the floors, under the beds, for the admission of air to this frequently unventilated region. It will be seen, therefore, that we rely upon the open windows, and these other means, for ventilation. So far as our experience has warranted a conclusion, the most perfect condition of ward atmosphere may be maintained with the means already adopted; and others for extraction, as by suction or by other processes, extra admission by various forms of ventilators, or moderation of force, as by perforated zinc plates, may easily be resorted to when a conviction of their necessity arises. Standing in the central line of the wards are two detached and open stoves, by which alone the warming of the wards is effected. They have descending flues which pass into chimney shafts within the walls. They have been carefully constructed in every particular, and, having a large radiating surface, are well calculated to effect their purpose. The water-closets, sinks, lavatories, and baths, are situated at the terminal extremities of the wards, and differ considerably from any others that I have known. The pavilions are approached from the central court by means of lofty, well-proportioned halls, having the staircase on one side, the ward nurses' room, and scullery on the other. These halls, as I before explained, should not exist in an exact specimen of pavilion hospital. The pavilion should terminate or commence at the door of the ward, approached by an arcade or staircase. Constructed as these halls are, however, there is little chance of hospital atmosphere, generated in the lower wards, contaminating that of the others. The floors are made of well-jointed oak, which, being waxed and dry-rubbed, will yield a striking advantage over the deal, washed floors of the hospital. Thus we shall, I trust, escape one of the most fertile sources of hospital contamination. The walls are faced with parian or Keen's so-called non-absorbent cement. Almost universal consent gives preference to this kind of covering, and warrants the superiority claimed for it on the ground of its slight absorption of malarious matter, and its capabilities for being readily cleaned.

My own preference would be for polished tiles, but they cannot be efficiently jointed. The spaces between the pavilions are about 73 feet wide, and looking into these are day room, and small wards, and more of these latter are found on an upper storey adjoining the pavilion staircases. Altogether the small wards are ten in number. The drainage has been carefully designed, running entirely outside the building, and no important outlet, from the wards or other parts of the hospital proper crossing under the building itself. The external features of the hospital, which may safely be pronounced of an elegant and striking character, are furnished by a free adaptation of mediæval architecture, and amongst the architect's many and important works will not least serve to substantiate his claim to the very highest rank in his profession. To say that he has handled his subject with consummate skill is doing little to explain the difficulties with which he had to contend. The site, previously pronounced by competent authority to be thoroughly unmanageable, he has bent to a very useful and efficient purpose, furnishing a very characteristic feature of the whole. The form or plan of building, whose peculiar excellence consists in the separateness of its various parts, he has, with consummate skill in the arrangement and concentration of the particular departments, secured efficient practical contiguity, so that in the widely separated pavilions he maintains the needful purity of atmosphere, yet keeps in view, as far as possible, and by the means I have already indicated, a large amount of administrative convenience. I direct your attention to the out-patient department with considerable satisfaction. I cannot but regard this as a very important element in the operations of a charitable institution like our own, and your inspection will, I anticipate, result in a verdict running up very closely to perfection. Irrespective of the palpable fitness of its different parts to their special uses, I find in its isolation from the rest of the hospital a very striking feature. There can be no contamination of the hospital atmosphere by the large numbers periodically congregated here; nor can the patients be in any sense disturbed by the noise and bustle necessarily occurring. Irrespective of the absolute benefit to the community by out-patient work, and the field it affords for the selection of proper cases for clinical treatment and instruction, I attach a higher value in a scientific point of view to this part of our labours than is ordinarily given. I know it is the fashion to deny its usefulness and to doubt the reality of the results. Notwithstanding the short time that is or can be given for the investigation of the cases treated, a very large measure of success is obtained. I further assert that a large proportion of these cases recover, allowing largely for phthisical and other instances of organic diseases having a necessarily fatal tendency. Of the curable cases a very large proportion do well, and this is abundantly proved by the ability with which our large population seek dispensary assistance. And these results are attained under confessedly most disadvantageous circumstances—the patient still dwelling in the same unhealthy locality, still breathing the same contaminated atmosphere, still subsisting on the same innutritious or ill-cooked food, and still pursuing the same wearying and exhaustive occupations, the only difference being, so far as I can ascertain, the administration of the prescribed medicine. Now, with the school of practitioners, who, as I believe unfairly, decry drugs, it is the fashion to attribute much, if not all, the patients' recovery to the rest and other attendant circumstances of improved hygiene, and still not hesitating to call to their aid the somewhat antiquated *vix medicatrix*, or restorative tendencies of the system. But in the instances with which I am at present dealing it is impossible to assert the operation of these agencies in the production of the result—the sole causes capable of influencing the morbid condition of the sufferer are the drugs which are introduced into his system. A careful, and I believe an important estimate of the results of out-patient work which has fallen to my lot has impressed me with a firm belief in the importance of its results, and I rejoice to find that this field of inquiry not merely for therapeutic investigation, but for the more general cultivation of scientific medicine, is attracting serious attention. One of our most distinguished associates has recently published a most valuable work [by Dr. E. W. Greenhow], derived, I feel I am warranted in saying, mainly from this neglected field of inquiry. I am satisfied that those who can devote the time to its cultivation, and the remark applies mainly to the juniors of our hospital staff, will reap an abundant harvest. It is really a question of time, which being granted equal minuteness may be attained as in any other branch of investigation, and though the circumstances in

which the out-patients are placed interfere much with the therapeutic result, it must be admitted that when success is attained the argument is greatly strengthened. Fortunately the current so long stagnant, or setting in a backward direction, has resumed its normal flow, and it should be one of the duties, indeed the privilege of this great association to guide and moderate the stream in a legitimate course. No town hospital will hereafter be completely fitted for the discharge of its beneficent functions unless there be associated with it a convalescent establishment at some distance in a country situation. Thither the recovering patient may be regularly transferred at once, to make way for other admissions, and more rapidly to accomplish their own restoration. Convalescent hospitals may be of two kinds, those which are purely and properly so, depending solely for their results on the renovating influences of purer air. The protracted rest the patient recently treated in the town hospital in whom the turn to convalescence has been thoroughly established, but who is not yet qualified to face the duties of his every day life, constitutes another of the advantages afforded by those establishments. The second class is made up of those institutions where it is proposed to supplement the efforts of the hospital practitioner by the use of mineral or other baths, or by the internal exhibition of various medicinal waters. We are fortunately so circumstanced, that within comparatively easy distance we have the justly celebrated springs of Harrogate and Buxton, both highly curative of many internal and external maladies. At Ilkley, in its pure water and exquisite mountain air, we possess a second Malvern, in no way inferior to its type in the renovating results produced upon various forms of ailment. At each of these three are hospitals for the reception of the poor, and at Scarborough and Coatham we have marine infirmaries, perfectly available for our many purposes. These latter institutions it has been said might have rendered unnecessary the establishment of special convalescent hospitals; but the function of the one class will not be interfered with by the existence of the other. Abundant claimants will ever appear for all the accommodation these in their separate departments can afford. Of the former class we have for some time had a temporary hospital open, which will now be transferred to a larger and more extensive establishment recently completed. This has been erected within a short distance of the town, and in a very healthy locality, at the sole expense of one of our distinguished fellow-townsmen, and by him dedicated to public use. It is constructed to accommodate one hundred convalescents, and is supplied, so far as I can understand, with every needed appliance. The honest hospital patient desires as speedy a return as possible to his remunerative toil, and many, no doubt, are tempted, under the pressure of family necessities, too soon to make the effort. Before the *sequelæ* of disease are thoroughly eradicated, or the consequent debility entirely recovered from, over-exertion favours relapse, or prevents the complete restoration of physical power. It may be that the premature return to the badly-ventilated workshop, where the artisan patiently endeavours to provide for the wants of those depending upon him for daily sustenance, or to the deteriorated atmosphere of his confined dwelling, in which he vainly seeks the renovation of his exhausted powers, tend to rekindle the scarcely extinguished embers of disease. To all these evils the convalescent hospital or the watering-place infirmary affords an efficient and ready remedy, and when honestly adopted yields to the community, whether giver or receiver, an unmixed good. But we must not shut our eyes to the fact that we have another and very different class of our hospital population to deal with. All charitable institutions are liable to abuse, and none of these so much, in my opinion, nor so detrimentally, as the convalescent hospital proper. Care, then, must be taken that the impostor does not establish his residence, and with equal vigilance the incurable must be excluded. If allowed facile admission they will completely destroy the usefulness which these very valuable institutions are capable of exercising, and convert into a crying abuse the otherwise beneficial agency of these asylums. Wherever convalescent establishments are erected for their special purpose they should be constructed on a plan as little resembling the regular hospital as possible. The reasons warranting this are obvious. I cannot, however, endorse the directions of Miss Nightingale, that in aiming at the above, the requisite for ventilation, and, to a very large extent, the abundant space established as necessary in regular hospital construction should be rejected here. I do not assert that the same cubic space or superficial area are equally needful for the convalescent as for the invalid, but a large difference cannot, in my opinion,

be safely made. If small wards in hospitals are objectionable on the ground of difficulty of ventilation, and if curtains are likewise undesirable, and, for the same reasons, I see no excuse for their adoption in convalescent hospitals; and I am glad to find that in the new institution to which I have referred these mistaken views have been discarded. Houses of this description may be erected which will suggest very little association to the mind of the convalescent with the painful memories of the hospital he has recently quitted; but in attaining this most salutary result, we need not thoroughly abandon those principles we have contended for as essential in the construction of the regular hospital, and which I believe cannot be safely disregarded in designing these kindred establishments.

Dr. Chadwick's address was listened to with the utmost attention, and the sympathy of the profession will be with him in the sudden affliction he has met with. After his address he was hastily summoned from Leeds to the sick bed of a married daughter, and, as it afterwards proved, to her death-bed. The circumstance naturally made a very deep impression on the large gathering of medical men.

SECOND DAY.

On Wednesday, Dr. Sibson resigned the Chair of the Council to Mr. Husband, of York. On him then devolved the duty of presiding in the unhappy absence of Dr. Chadwick.

It was then decided that the next year's meeting should be held at Newcastle-on-Tyne, and that Dr. Charlton should be the President.

The hospitality of the Mayor of Leeds was acknowledged by electing him honorary member.

Sir William Jenner, M.D., F.R.S., delivered the Address in Medicine—an able and eloquent statement of our progress in the art of medicine.

In the evening the *soirée* took place at Victoria Hall, when a large number of members and visitors were present.

Trip to West Riding Asylum.—Nearly 100 gentlemen accepted the invitation of Dr. Crichton Browne to visit the asylum, of which he is the able Medical Director. After luncheon the party went over the grounds, and were met on the lawn by some 700 of the patients and a number of visitors. The choral choir of the asylum gave a promenade concert on the occasion.

THIRD DAY.

On the third day (Thursday), about 150 members attended a breakfast on the invitation of Mr. Baines, M.P., a Vice-President of the National Temperance League; at ten o'clock the third general meeting of members took place, and lasted until one; at two, Dr. Beatty's Address in Midwifery was delivered; and at three the Sections met. It was half-past five before many of the Sections adjourned, and by six o'clock the members were assembled in the Victoria Hall at the annual dinner, when Dr. Heaton presided in place of Dr. Chadwick.

Dr. WATERS (Chester) read the Report of the Representation Committee. Before doing so, however, he stated what the action on the question had been during the last two years. In 1867, Mr. Husband, the present President of the Council, suggested that a sub-committee should be formed with the view of ascertaining how far it was desirable that the profession generally should be directly represented on the General Medical Council. Dr. Waters proposed that the Report be adopted by the meeting.

Dr. BATEMAN (Norwich) having seconded the resolution, it was supported by Prof. HAUGHTON (Dublin), who expressed his entire concurrence with the Report, but in a friendly spirit suggested that a slight addition to it should be made. He thought that by agreeing to the following amendment the profession would be more certain to secure a large working majority on the future Council:—"That the Report of the Representation Committee be adopted, with the addition of the following resolution:—"That the members of the British Medical Association are of opinion that graduates and licentiates of the Universities and Medical Corporations should have the power of electing their own representatives on the Medical Council."

This amendment was seconded by Dr. MARTIN (Warrington). After which Dr. SIBSON stated that he had frequently heard the opinion expressed that the speaking power of the Medical Council was a great deal ahead of the working power. With regard to the objection to the views of the Committee being carried out on the ground that the talking power would be increased and not the working power, he remarked that he was intimately acquainted with the members of the Council of that Association, and declared that he knew of no more practical body of workers. As a body he was quite certain that the members of the profession, in their election to the Medical Council, would choose not talkers, but workers.

After a brief discussion, it was agreed that the Report should be adopted, and the amendment be submitted as a resolution.

Mr. HECKSTALL SMITH was of opinion that it would be undesirable to adopt the motion without very much more consideration than they had. He feared that Dr. Waters was too sanguine in his belief that the Government would so readily carry out the views of the Association. In his opinion Prof. Haughton's resolution would lead to what would, in fact, be a double representation of the profession on the Medical Council, and he was sure that it would result in the postponement of the success of their great object, which wore now such a promising aspect.

The discussion was continued by Dr. SIBSON, Dr. HESLOP (Birmingham), and Dr. LEES (Ashton-under-Lyne), the last-named gentleman remarking that it was no use going into a measure which could not be attained.

Professor HAUGHTON having replied, the resolution was submitted to the vote and adopted.

LAST DAY.

On Friday (the fourth day) the proceedings were brought to a close. Mr. Nunneley delivered the address in Surgery at 10 a.m. The Sections continued their work at 11. At the concluding general meeting, at 3.30 p.m., various formal business was got through, and it was proposed that the vote of the day before, on representation in the Council, should not be binding in communications with Government. A resolution of condolence with Dr. Chadwick in his heavy affliction, and regret that so sad an event should have deprived the Association of his presence in the chair, was unanimously adopted, and ordered to be forwarded by the Secretary to the esteemed President.

In the evening Dr. Heaton, president of the Leeds Philosophical Society, entertained the members and a large circle of visitors at a *conversazione* in the hall of the Society.

Trip to Harrogate.—About one hundred members were magnificently entertained by the medical gentlemen of Harrogate at the Queen Hotel. They had a special train, and found on arrival carriages at their disposal. They were received at the hotel by Drs. Myrtle, Bennett, Deville, &c., and expressed great delight at the hospitality they received.

We add an abstract of the address of Mr. Nunneley, of Leeds, the event of the day.

Mr. NUNNELEY said that as last year physiology was the theme, he had this year assigned to him, what was to them of as much immediate importance, the duty of addressing them on Practical Surgery, and of pointing out, as far as might be in the limits of an address, the improvements and alterations which in recent times have taken place in it, both as a science and as an art. He recollected the time when the stethoscope was an almost unknown instrument, and well remembered the hesitation there was in arriving at an opinion as to its value as a means of diagnosis; yet it had done more for mankind than many a battle fought and won, which had ennobled and made famous its general throughout the length and breadth of the land. Forty years ago the microscope was little more than a toy. Now it had become almost perfect, and its most skilful and ardent manipulators were those of the medical profession. The ophthalmoscope was of so recent introduction that it might safely be said that the majority of medical men had not mastered the difficulties of its application, yet it had already revolutionised the diagnosis and treatment of several of the most serious affections of the eye. The laryngoscope had enabled them to illuminate the larynx and trachea, which until then were closed, dark, and unapproachable to any of our

senses. Though the endoscope had, as yet, not accomplished all that its votaries had said in its favour, and, in the hands of the practical surgeon had, he believed, so far failed to be of very much use in illuminating the deeper cavities of the body, it was doubtless the forerunner of improved instruments which would enable them to light up more than one of the hollow organs, and see what was there going on. Then, again, the sphygmograph, as a help to precision in estimating the true value of the variations in the pulse and the measure of the heart's action in a more exact manner than digital touch alone could accomplish, was an application of physiological and mechanical skill which was worthy of great praise. Nor must the employment of delicate thermometers for ascertaining calorific variations under different abnormal conditions be passed over without mention, as in many cases tending to help diagnosis and prognosis. After speaking of thrombosis and embolism, and pyemia, he touched upon the efficacy of ovariectomy in the cure of dropsy and of stricture of the urethra, which now—thanks to the simple, innocuous, and, comparatively speaking, painless operation, and the ingenious instruments devised by Mr. Holt—in the great majority of cases, even those of the worst description, a speedy and permanent cure might be obtained. It is impossible to enumerate all the subjects on which Mr. Nunneley touched in his able and comprehensive paper. In reference to the modern surgical operation of removal of the entire tongue, he said that up to the present time he had removed the entire tongue nineteen times without any untoward symptom following in a single instance. In most cases the patient had not required any after treatment, being able to sit up on the following day, and in ten days to be considered well. In the majority of operations not a drachm of blood had been lost. After speaking of by what slow steps our forefathers progressed in attaining the knowledge and practice by which bleeding from a wounded artery was now, in ordinary circumstances, so easily stopped, Mr. Nunneley said that the ligature, as employed for many years past, was so simple, so easy of application, and, in the majority of cases, so satisfactory, that many surgeons were still quite contented with it; yet that it had grave defects was undeniable. A means for obtaining a certain and secure closure of a bleeding artery, in which no foreign substance shall remain, or, if remaining, shall be innocuous, had been a grand desideratum with all practical surgeons. Cold, exposure to the air, styptics of various kinds, and cauteries, actual and potential, were all useful when the bleeding vessel was of small size; but, as every surgeon knew, were not to be depended upon when the vessels were of more than a moderate calibre. To their learned associate, Sir James Simpson—(loud applause)—to whom the world was so much indebted, that had he been half as successful in destroying and making miserable human life in warfare, as he had been in saving suffering and conferring blessings upon distressed humanity, he would have been amongst those whom the State delights to enrich and ennoble—the profession owed a most ingenious method of arresting bleeding from divided blood vessels without the use of ligatures. He suggested the plan of closing the open vessel by pressing it against bone by a long steel pin carried through the soft tissues on each side of it, or by carrying the pin under the vessel, and twisting a loop of wire over its two ends in such a way as to allow of its being easily removed, when desired, without disturbing the parts. As to accupressure, for himself he must candidly confess that he had never felt sanguine that it possessed all the advantages its advocates claimed for it. For upwards of eighteen months he believed accupressure had not been used in the Leeds Infirmary. How far the method of soaking a fibrous material in carbolic acid, as suggested by Professor Lister, and the still more recent one of employing catgut so treated will accomplish all he anticipates, time alone would show. There remained but one other subject to which he proposed to allude. It was, however, an important one. He owned to approaching it with some hesitation and reluctance. He referred to the recent—should he venture to say fashionable—method of treating wounds by what had been called the "antiseptic treatment," by which it was to be feared the sound physiological and pathological doctrines and practice of the last generation of British surgeons were unheeded, and in danger of being temporarily forgotten by what seemed to him unsupported fancies, which had little other existence than what was found in the imagination of those who believed in them. That carbolic acid was a specific against purulent infection, or that it acted by destroying septic germs, he believed to be a fallacy, an *idola theatrici*; but that it was a useful agent, among many others, which had a like effect

with it, in coagulating animal matters, in accordance with its strength, stimulating the parts and contracting the smaller vessels, so as to arrest the oozing of blood and serum, he readily admitted, and if the claims for it were limited to this action, he believed that no one would be inclined to doubt its value. During the last three years since the "antiseptic treatment" had been in vogue, he had not allowed one of his patients to be treated with carbolic acid, while his colleagues had very extensively employed it, and he might say, at least at one time, possessing the full amount of faith necessary for securing success, fairly tried it. The result was, that his cases without it were as good as theirs with it. Had he during that time found their success with the antiseptic treatment was greater than his without it, he gladly should have availed himself of it; but he did not. On the other hand, as an additional proof that it had not been so, it might be mentioned that lately the omission of it, even in large operations, had been more and more frequent, until now its employment had become the exception instead of the rule.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your number for June 16th, 1869, appeared a communication from the present writer suggesting the employment of spectrum analysis in various branches of medical investigation. When penning that letter I was under the impression that the spectroscope had not been previously employed by medical observers.

The issue by the New Sydenham Society of their "Biennial Retrospect," which has just taken place, has been the means of enlightening me considerably on this point. From the examination of that publication it appears that the spectroscope had been resorted to on the Continent by Sonnenschein and others in the medico-legal examination of blood stains. Max Jaffé, and, in our own country, Dr. Thudichum, have also availed themselves of this method of analysis for the promotion of physiological and pathological science; but the results attained by those investigators having been published in journals and periodicals not generally accessible, I was not kept quite *au courant* with the march of medical research in this particular direction.

I offer the above remarks lest I should be accused of attempting to circulate ideas at second-hand.

Very truly yours,

J. R. M'MAHON MURPHY, A.B., M.B.,
Moderator in Natural and Experimental Science, T.C.D.

Thurles, July 24.

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS.

THE DUBLIN MILITARY PRISON.

Mr. KIRK asked the right hon. gentleman, the Secretary of State for War why no allowance appeared for the medical officer of the military prison of Dublin, the duties appearing to be performed by any officer of the medical staff; whether Surgeon-Major Tufnell, the medical officer performing those duties, has not completed nearly twenty-seven years medical service, nearly all in Dublin, on the full pay of his rank; was he not the only medical officer on full pay in charge of a military prison; did he not hold civil appointments in Dublin, and was he not also extensively engaged in private practice in that city; was there any reason affecting the interests of the service rendering it desirable that he should continue to enjoy such exceptional privileges; and did his retention on full pay in charge of a military prison stop promotion among other medical men; and the employment of a half-pay medical officer in the prison of Dublin?

Captain VIVIAN replied to the question in the absence of Mr. Cardwell. He said—In answer to the question of my hon. friend, I have to say with respect to the first paragraph that Surgeon-Major Tufnell does perform the

duty of medical officer of the military prison at Dublin, and that he has done so since the year 1846. He is paid as surgeon-major on the medical staff. With respect to the second paragraph, it is true that Surgeon-Major Tufnell has performed those duties not for twenty-seven years, but for twenty-eight years' completed service; but until 1860 he was only assistant surgeon, having foregone his promotion in order to retain his appointment. In 1860 he was promoted to the rank of surgeon in compensation for the loss of a Regius Professorship which he held in Dublin under Royal commission. With respect to the third paragraph, I have to state that he is the only medical officer on full pay in charge of a military prison, but that he holds that position by virtue of his appointment to it in 1846, by way of compensation for loss of promotion. That appears to have been admitted as a fact. With respect to the fourth paragraph, it is true that Surgeon-Major Tufnell holds different other appointments in Dublin. He is governor of the City of Dublin Hospital, one of the Council of Examiners of the College of Surgeons in Ireland, and has also a large private practice, but I do not know, and we have no reason to suppose, that these duties at all interfere with the performance of his public duties. I think I am bound in justice to say that so far as we are aware they do not interfere with his public duties. With respect to the fifth paragraph I have to state that Surgeon-Major Tufnell claims a vested right in his appointment, and says he is entitled to retain it as compensation for the loss of his Regius Professorship to which I have before alluded. With respect to the sixth paragraph, it is true the appointment of Surgeon-Major Tufnell stops the employment of a half-pay medical officer at the prison in Dublin, but it does not stop promotion among other medical men, because Mr. Tufnell is on the superannuation list. In 1874, however, he will have arrived at an age when his retirement will be rendered compulsory. Until then he can continue to retain his appointment, and as he has this vested right to the appointment it is not likely he will give it up.

Medical Cleanings.

FRACTURE OF SKULL; FRACTURE AND DISLOCATION OF HUMERUS OF LEFT ARM, AND FRACTURE AND DISLOCATION OF RIGHT.

C. B. Frazer, M.D., of East Saginaw, Mich. (*Am. Jour. Med. Sciences*), was summoned on October 11, 1867, to a lad of fifteen years, who had been caught by the crank of a balance-wheel in a shingle mill, and was taken up perfectly insensible. The following injuries were found: An incised wound of the head, about three inches in length, commencing about the middle of the superior portion of the temporal bone, and extending downward, backward, and upward, forming a semi-circular flap about an inch and an eighth at the widest portion; another fracture was found near the parietal eminence; and at the junction of the parietal bones with the occipital, a bloody tumour had formed, about two inches in diameter at the base extremities: a fracture of the external condyle of right humerus; fracture of the coronoid process of ulna, and a backward dislocation of elbow; the annular ligament was ruptured, and a dislocation of radius from ulna. Left arm: a downward dislocation of humerus, and upon rotating it after reduction, crepitation was very perceptible at the joint, showing a fracture of the anatomical neck. Inferior extremities were somewhat contused but not fractured.

Chloroform was administered, and he proceeded to reduce the fractures and dislocations first. The right arm, after reduction, was placed upon an angular splint. The left was secured to the side by a body bandage.

The skull was next trephined, after having made a crucial incision, and dissected up the flaps. The depressed fragment, half an inch long, and three eighths of an inch wide, was removed with a pair of forceps. The dura mater was entire. The wounds were now closed, and, strange as it may appear, not one particle of suppuration occurred in either of them. They all closed by "immediate union."

At the expiration of the second week the body bandage was removed, and the arm allowed to rest beside him in bed.

In about four weeks he visited the office of Dr. F. for further treatment, and was there as often as once a day up to Nov. 25, 1867, when very nearly complete movements of the elbow-joint were secured, by cold douches, passive motions, and friction. The shoulder-joint is, to all appearance, as natural as before the accident.

HYDATIDS.

THE *Archives Générales de Médecine*, for January and February, contains articles on the frequency of hydatids in Iceland. This disease is very common in this colony from eating hydatid mutton, pork, and drinking water from ponds which sheep and dogs frequent, and therefore everything connected with it is of the greatest interest. In Iceland, Dr. Leared found that one of every five deaths was from this disease. Dr. Finsen, the author of these articles, found that, out of 7,539 cases of disease, 280 were suffering from hydatids; and among 56 persons, living in different parts of the country, 13 were affected. There, as in this colony, the liver is the organ most frequently affected—176 times, in 255 cases, the cavity of the abdomen (the origin being uncertain) 54, and the lungs in 7. In this colony, the lungs and the omentum stand next in frequency of liability to the liver. This may be accounted for in two ways—either from their becoming implicated when the upper part of the liver is affected, or from the animal being deposited in them either primarily or secondarily. The gastro-hepatic omentum seems to be the part most liable in the abdomen; but it is often extremely difficult to determine whence the cyst has originated until after death.

In the case of a person of the name of Brown, brother to a stonemason living at Carlton, the cyst presented all the appearance of ascites, and when tapped, eleven quarts of fluid were drawn off. The history of the case seemed to point to the under part of the left lobe of the liver as the place where it originated, but, after death, a cyst not larger than the fist was found in the lower part of the right lobe.

Finsen observes that, in nearly all the cases, he found only one tumour, and that it was rare to find hydatids in the lungs.

He has drawn up a long list of the symptoms which may be experienced during the growth of the cysts; but, in this colony there is a frequent absence of symptoms—the person suffering but little in health.

When the cyst is situated in the lungs, and near the large bronchial tubes, there may be cough of a spasmodic nature, and generally, unless it is accompanied with some alteration in the bronchial tubes, or the substance of the lung in its vicinity, there is no expectoration; when situated in the liver, jaundice ensues, if the large biliary ducts are pressed on; when pressing on the stomach, some interference with digestion; and when on the intestines, more or less obstruction. The presence of a smooth, oval, elastic tumour is often the only sign, and there may be but little pain. There is, however, a symptom which I have noticed in the course of watching a large number of cases, and, when met with, it may be considered as diagnostic that the tumour is hydatid.

If the patient is kept for some time without drink, and caused to walk a considerable distance, but not so fast or so far as to cause pain or uneasiness, if the tumour is then measured, it will generally be found somewhat smaller. If he be then placed in a warm bath, the cyst will be found in the course of fifteen or twenty minutes (the more superficial it is the quicker) to enlarge, and it may even attain a considerable size. It is owing to the tendency that the hydatids have to absorb moisture, that patients complain, in this country, in damp weather, of fullness of the cyst, and it then evidently increases in size. If the hydatid is dead, there will be little or no alteration.

HYPODERMIC INJECTIONS OF MORPHIA IN LABOUR.

Dr. E. KOSMAN, Leipzig (*Am. Jour. Obstetrics*), considers hypodermic injections of the sulphate of morphia superior to any anæsthetic during labour. He injects very slowly one-eighth to three-fifths of a grain in the thigh. The indications for the injection are: Primiparæ, narrow pelvis, spasmodic contractions, and painful complications generally.

THE PONS VAROLII THE NERVOUS CENTRE OF GENERAL CONVULSIONS.

H. NOTHNAGEL (*Virchow's Archives*) arrives at the following conclusions in regard to the *nervous centre of general convulsions*, which are derived from actual experiments. The centre of general convulsions is situated in the substance of the pons. Its lower boundary is corresponding to a section at the height

of the inferior border of the pons. The faculty to perform the function of a centre of spasms is to be denied to the substance of the medulla oblongata.

Finally, he endeavours to prove that the spasms are produced by way of reflex. In some instances the section of the medulla oblongata had been made below the pons, the animals remaining absolutely quiet. Again: the convulsions occurred if the section had left a portion of the pons connected with the medulla oblongata, showing the centre of action to be situated outside of the medulla.

At last the anatomical condition of the region of spasms is confirmatory to the view of reflex action. The region nearly corresponds to the situation of the gray nuclei and root-fibres of the sensitive cranial nerves. While the nuclei and roots of the motor cranial nerves are near the raphe, those of the sensitive nerves are more lateral. The root-fibres of the portio major trigemini, in particular, descend, according to Schroeder van der Kolk, through the whole length of the medulla. This anatomical condition, it must be conceded, is no direct proof of a reflex action, but it renders it admissible and plausible.

From all this it seems that the convulsions following the injury of a defined region on the floor of the fourth ventricle are to be explained as spasms induced by reflex action.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — At the ordinary general meeting, held on the 29th ult., the following members of the College were elected Fellows:—John Thomas Arlidge, M.B., Lond., Newcastle-under-Lyme; John Cockle, M.D., Aberdeen, 13, Brook-street, London; Matthew Alexander Eason Wilkinson, M.D., Edin., Manchester; John Langdon Haydon Down, M.D., Lond., 39, Welbeck-street, London; William Alexander, M.D., Edin., Halifax; William Henry Ransom, M.D., Lond., Nottingham; Owen Daly, M.D., Dublin, Hull; Henry Day, M.D., St. And., Stafford; George Fielding Blandford, M.B., Oxford, 3, Clarges-street, London. Henry Maudsley, M.D., Lond., 33, Queen Anne street, London; William Henry Broadbent, M.D., Lond., 23, Upper Seymour-street, London. At the same meeting the following gentlemen, having passed the required examinations, were admitted Members of the College:—James Watt Black, M.D., Edin., 15, Clarges-street, Piccadilly; Francis Cooke, M.D., Edin., Cheltenham; Thomas Trollope, M.D., Camb., St. Leonards-on-Sea; and Joseph Hogg Baller, M.D., St. Andrew's, 13, Gilston-road, West Brompton.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The Directors held their Quarterly Court on Wednesday, July 14th, Dr. Burrows, F.R.S., President, in the chair. It was announced that the large sum of £1,427 10s. had been voted for the half-yearly grants, being £177 in excess of the sum distributed last half year. Fresh applications were made from seven widows and twenty-six children, to whom the sum of £236 10s. was given. There are at present fifty-seven widows and forty-nine children receiving relief, an increase of five widows and twenty-six children during the half year. One widow has died, another is no longer eligible, and three children, having attained the age of fifteen, have ceased to be eligible for relief. The Directors earnestly appeal to the wealthier members of the profession to assist them by their contributions, without which the funds of the Society will not suffice to meet the continually increasing demands for relief. Contributions may be sent to the office, 53, Berners street, London, W.

THE EMPRESS CHARLOTTE.—A melancholy little incident is related of the ex-Empress Charlotte. This unfortunate Princess has been staying for some time at Spa. The other day she insisted with such vehemence on playing at roulette that it was impossible to restrain her. On approaching the table she deliberately placed a gold piece on the number 19. The Emperor Maximilian was shot on June 19. The wheel turned, and, though 37 chances were against her, she won. She smiled sadly, took up the money, and quietly left the room. On her way out a poor man passed by. She gave him all the money, with the injunction that he was "to pray for him." It is known that the Empress Charlotte never pronounces the name of Maximilian.—*Pall Mall Gazette*.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—The annual meeting of the above association was held on Wednesday, at the Freemasons' Tavern; Dr. Rogers, the president, in the chair.

The first annual report of the council, which was read, stated that if the association could not boast of any great practical achievement, their labours had not been altogether in vain, while the mere union of medical men for the attainment of a common object had been openly recognized as an important event in the current history of the profession. The council had unceasingly advocated the necessity of an adequate and, as far as practicable, a uniform payment in proportion to work of the medical officers generally, and the vital importance of permanence of appointment in all cases. They had reason to believe that some boards of guardians were reconsidering the salaries of their officers, but no general improvement, however, could be hoped for in this respect till the House of Commons accorded to the medical officers the *status* of Civil servants of the Crown, and directed the Poor-Law Board to fix the salaries, which should be paid altogether, instead of half only, out of the Consolidated Fund. But this could not be done until the poor rates were equalized, a policy to which the present head of the Poor-Law Board was fully committed. The report further stated "With regard to permanent appointments your council have the satisfaction of knowing, from Mr. Goschen's own lips, that he is opposed to the differences in the terms of appointment which now exist; and they do not doubt he will use his best endeavours to place all medical officers on the same footing in this respect. Poor-Law questions are, at the present time, exciting considerable attention, more particularly as they affect the metropolis. And well they may, seeing that the pauperism of the metropolis—Mr. Goschen himself being witness—has increased nearly 50 per cent. in three years. The measure now before Parliament, to amend Mr. Hardy's Metropolitan Poor Act, 1867, will, no doubt, become law this session; and ere long your council hope to see the dispensary system fairly on its trial. They rejoice to know that the President of the Poor-Law Board is in favour of the system." After cordially congratulating their Irish colleagues upon the success which had attended their exertions, the report, which was adopted concluded thus:—"The association, moreover, is a standing protest against the wrongs of the service. Its power is not inconsiderable even now; how greatly it would be increased were its numbers doubled—trebled; or if it included in its ranks the entire service of 3300 officers, none can tell. Such unanimity is beyond hope; but if every member would, at this time, do his utmost to obtain recruits, some approach to it might be soon attained." The receipts during the year had been, 271*l.*, and, notwithstanding the expenditure had been exceptionally heavy, a balance of 58*l.* remained in hand. The Chairman then addressed the meeting at great length, in the course of which he said they had given considerable impetus by their unanimity and critical investigation to the settlement of the question of cubic and floor space; that they pressed successfully upon the Poor-Law Board through the Lunacy Commissioners the issue of an instructional letter which laid down a more humane and decent mode of dealing with pauper lunatics when requiring certificates previous to removal to asylums, and that after great trouble they had succeeded in showing the Poor-Law Board the advisability of establishing a uniform dietary suited for the different classes of workhouse inmates. He referred in eulogistic terms to the important services of the "veteran reformer, Richard Griffin," and passed on to ask when would the medical bodies in this country see the justice and advisability of doing as the Irish corporations had done, reminding them of the good they would do by extending to them the right hand of sympathy.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—The following communication, which has been addressed to the Royal College of Physicians by the Poor-Law Board, is one of considerable interest to young medical men, who are thus enabled to obtain both a medical and a surgical qualification by the single course of examinations instituted by the College in accordance with the Act 32 Henry VIII., cap. 40:—"Poor-Law Board, Whitehall, S.W., July 16. "Sir,—I am directed by the Poor-Law Board to acknowledge the receipt of your letter of the 7th inst., in which you transmit for their information a copy of the form of licence to be granted henceforth by the Royal College of Physicians, London. I am directed to state that the Board will in future recognize the licence in question as conferring the right to practise both medicine and surgery, and thus rendering the holder of such licence legally qualified for the office of medical officer under the regulations of the Board.—I am, Sir, your obedient servant, ARTHUR PEEL, Secretary.—Henry A. Pitman, M.D., Esq., Registrar, Royal College of Physicians, Pall-Mall East, S.W."

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

DISPENSARIUS.—Your letter does not appear to us in any respect to affect the merits of the controversy, and, being personally offensive, we are compelled to decline it.

DR. KELLY, Kiloconnell.—In the defective state of the law you have no remedy against a bone-setting quack, unless he should bring himself within your reach by either of two legal proceedings. If he should use publicly any title implying that he is a legally qualified practitioner, you may obtain a conviction under the Medical Act. If he treats any case unskillfully, the persons aggrieved may indict him for malpraxis; but it would not be open to any third person to do so.

DR. M'MANUS, Ballymahon.—The Poor-Law Medical Officers' Superannuation Bill only waits the Royal assent.

ERRATA.—In Dr. Purdon's Paper on "Vegetable Parasitic Diseases of the Skin," in our last; page 75, first column, lines 9, 29, 54, for "alopecia acuta," read "alopecia areata;" line 17, for "epidemics," read "epidermis;" line 29, for "decalvans," read "decalvans;" line 49, for "time," read "tinea;" line 60, for "vesicolor," read "versicolor."

DR. T. W. MARTIN, in our next.

COMMUNICATIONS, Enclosures, &c., received from Mr. Annandale, Edinburgh; Mr. Adams, London; Mr. Wilkinson, St. Mary's Hospital; Dr. Ross, London; Dr. Palfrey, London; Mr. Lewis; Mr. Rivington, London; The Secretary to the Society for Relief of Widows and Orphans of Medical Men; The Secretary of the Devonshire Hospital; Dr. McEvoy, Balbriggan; The Registrar General, Mr. John Pollard, Metropolitan Board of Works; Mr. Davenport; Dr. Jolliffe, Shepherd's Bush; Dr. Purdon, Belfast; Mr. Monckton, Wadebridge; Mr. Barnes; Dr. Faber; Dr. Parvin, Indianapolis; Dr. Pitman, Royal College of Physicians; Dr. Alexander Chain, Liverpool; Dr. McGrigor Croft, St. John's Wood; Dr. Burder, Bristol; Dr. Drysdale; Dr. Rogers; Dr. Robinson, Hounslow; Dispensarius; Mr. Kelley Kiloconnell; M.A.B., London; Mr. Tichborne, Dublin; Dr. Macmanus, Ballymahon; Dr. Edwards Crisp, Chelsea; Dr. Maunsell, Dublin; Dr. Martin; Dr. P. Heron Watson, Edinburgh; Dr. Waring Curran, &c., &c.

DR. EDWARDS CRISP AND THE CARMICHAEL PRIZE ESSAY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although you refuse to insert the abstract of the letter I placed before the Medical Council, and my letter to Mr. Hargrave, you will surely allow me to correct the misrepresentation you have made respecting my *claims* before the Council of the Royal College of Surgeons, Ireland; I have never made any *claims*; I have never opposed the adjudication, nor the non-adjudication of this Prize on pecuniary considerations, and I have never said that my essay was worthy of the Prize. I have undertaken the exposure at great trouble and expense, solely on public grounds, as you will see, if you will suspend your judgment for a short time.

Yours obediently,
EDWARDS CRISP, M.D.

Chelsea, July 31, 1869.

**Our correspondent appears to have misunderstood our note in last week's Journal. The *claims* referred to by us were not those of a pecuniary nature, but those which Dr. Crisp has before, and is still endeavouring to press upon the Royal College of Surgeons, Ireland,—viz., the readjudication of the Prizes.

We refrained from an expression of opinion upon the point at issue, and we declined to print the letter of our correspondent, for the simple reason given in our last.

VACANCIES.

Royal Hospital for Diseases of the Chest.—Honorary Physician. Election September 7th.
Royal Infirmary for Children, S. E.—Honorary Physician. Election August 4th.
Darlington Hospital.—Resident Medical Officer. Salary £10, with furnished apartments.
Royal Portsmouth Hospital.—House Surgeon. Salary £120, with board and residence.

BOOKS RECEIVED.

Scientific Associations, their Use, Progress, and Influence. By H. J. Fotherby, M.D., &c., London: Bell and Daldy.
Report on the Sanitary Condition of St. Giles. By George Ross, M.D.

Quarterly Sanitary Report for Glasgow and Districts.
The California Medical Journal; The Homeopathic Review; L'Union Medical; Pharmaceutical Journal, &c.

Deaths.

ALDREN.—On the 13th ult., at Euchumpilly, Central Provinces, India, Robt. Aldren, M.B., C.M. Edin., Assistant-Surgeon Madras Army, and Civil Surgeon Upper Godavry District, aged 24.
HELE.—On the 17th inst., Henry H. Hele, M.R.C.S.E., of Teignmouth, aged 78.
JONES.—On the 17th inst., W.D. Jones, M.D., of Laneyeh, near Newcastle Emlyn, aged 77.
KIRK.—On the 25th ult., Geo. Kirk, L.R.C.P.Ed., of West Hartlepool, Durham, formerly of Middlebrough, aged 61.
ROBINSON.—On the 12th inst., Collings Robinson, M.D., of Cheltenham, aged 61.
SHIRLAW.—On the 25th of April, at West Taieri, New Zealand, J. Shirlaw, M.D.

THE INTRODUCTION OF THE CLAMP IN OVIARTOTOMY.

Mr. T. SPENCER WELLS writes as follows to the editor of the *Boston Medical and Surgical Journal*, in reply to a letter from Dr. Parks, inquiring who was entitled to the honour of having invented the clamp used in his operations in ovariotomy:—

"The credit of the introductions is due to Mr. Hutchinson, Surgeon to the London Hospital. He first used one in 1858. It was simply the common calliper of carpenters, which he used and left applied, handles and all. Then the handles were made movable, so that they could be taken off as soon as the clamp was fixed. Then I made the blades parallel, and did without handles. But afterwards returned towards the original form of clamp, altering the joint and the form of the opposing surfaces of the clamp until I arrived at that which I now use. You may see it figured in Dr. Druitt's *Vade Mecum*, ninth edition, 1865, page 541. I have now (January 25, 1869,) completed 300 cases. Of the

1st 100 cases,	64 recovered and	34 died.
2d 100 "	72 "	" 28 "
3d 100 "	77 "	" 23 "

Total 300 " 213 " " 85 "

A general mortality of 23 per cent., but it is very encouraging to note that the mortality has been steadily diminishing with increasing experience."

Since October last he has completed the operation of ovariotomy in 36 cases. Of the thirty-six women, 31 recovered and 5 died: and it is a remarkable fact that in every case in which the pedicle was long enough for him to use the clamp the patient recovered.

ECTROPIUM INTESTINORUM.

A mother, 21 years of age, was delivered of a male child, in which the following state of things existed:—From an opening two inches in length at the umbilical region, $\frac{1}{4}$ inch to the right of the umbilicus, and parallel to the linea alba, bulged out the greater portion of the intestines. Their coats were hypertrophied, and the abdominal walls were to such an extent contracted, as to allow only the admission of the small finger on both sides of the orifice. The rigidity of the abdominal wall did not allow of any stretching. It was an eight-months child, passed its natural secretions, fæces and urine. In the morning it vomited bile, and in the afternoon nursed at its mother's breast; its pulse was regular, as was also its respiration. The portions out were made up by the duodenum, jejunum, and ileum of the small intestines, and the colon and a portion of the rectum of the large intestines. The child died the day after its birth, having lived exactly 21 $\frac{1}{2}$ hours.—Geo. Fredigke, *Chicago Medical Examiner*.

OSSEOUS REGENERATION OF STERNUM.

DR. ENRICO BOTINI communicates to the *Annali Universali di Medicina* the particulars of the case of a soldier, æt. 30, wounded in the superior region of the sternum during the Italian campaign of 1866. The ball lodged, producing caries, necessitating an operation for its removal which exposed the pleural sac, the osseous walls of the sternum having been gradually absorbed, and a prompt recovery ensued, and new osseous tissue was formed analogous, in resistance to the touch, to the rest of the sternum.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also applied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under.....	£0	3s.	6d.
Per line afterwards.....	0	0s.	6d.
One-quarter page.....	1	5s.	0d.
Half ".....	2	5s.	0d.
One ".....	4	0s.	0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for insertion in this Journal must be at the OFFICE, ON SATURDAY, by Two o'clock.

LOEWENTHALS' NEWLY INVENTED AND REGISTERED

CHOCOLATINE

IS ACKNOWLEDGED BY THE BEST AUTHORITIES AS THE PUREST EXTRACT OF COCOA OBTAINABLE, Vide—*British Medical Journal*, April 3rd; and other Medical Papers Sold in packets, 9d., 1s. 6d., 3s., and 5s. 6d. each.

N.B.—A sample gratis by enclosing a stamped envelope to the WHOLESALE DEPOT, 70 FENCHURCH STREET, London, E.C.

Van Houten's Cocoa.

The only guaranteed Pure Soluble Cocoa, and better than any other Cocoa, Cocoa Extract or Essence, and Chocolate sold in this country.

Produces with boiling water *instantaneously* a most wholesome and delicious beverage. No milk required.

Dr. HASSALL tested and contrasted it with the best descriptions of Cocoa and Chocolate to be found in the English Market, and says:

"While the great majority of them consist of MIXTURES of Cocoa, Starch, &c., VAN HOUTEN'S is not only composed solely of the Cocoa Bean, but this of the finest quality. Although nominally dearer than many of the English preparations, from its purity, strength, and aroma, it goes much further, so that in the end it is really much cheaper: and from the smaller proportion of fatty matter present, and superiority of quality, it is well suited for use in Hospitals and other public Institutions."

Sold in round tins of one pound, half-pound, and quarter-pound, at 3s. 6d., 2s., and 1s., by all Grocers, Chemists, and Messrs. Spiers and Pond's Refreshment Rooms.

SOLE AGENT AND CONSIGNEE OF VAN HOUTEN'S COCOA, H. ESCHWEGE, 6 & 7 COLEMAN STREET, E.C.

Hospitals and Public Charities can have one-pound samples for trial free of charge.

CADBURY'S COCOA ESSENCE

Absolutely genuine, economical, being about three times the strength of the Homeopathic Cocos and French Chocolates ordinarily sold; suitable for the weakest stomach, owing to two-thirds of the Fatty Matter, which forms 50 per cent. of the Nib, being removed. "The richness is thus overcome in a manner far preferable to the impoverishment of the Cocoa by dilution or Adulteration."—*The Lancet*. "Cocoa treated thus will, we expect, prove to be one of the most nutritious, digestible, and restorative of drinks."—*British Medical Journal*.

C O C O A .

HANDFORD and DAVIES continue to Manufacture Cocoa precisely in the manner as in the year 1851, when the ANALYTICAL SANITARY COMMISSIONERS employed by the *Lancet* pronounced so favourably of it.

Pure Granulated Cocoa, in 1lb. packets, 1s. 2d. per lb.

Homeopathic ditto, in 1lb. canisters, 1s. 2d.

This latter is most convenient for gentlemen in chambers, and for use at sea, being prepared on the instant by the addition of boiling water, and, though not entirely cocoa, will be found very superior to similar manufactures.

Cocoa Nuts, 1s. per lb.; Cocoa Nibs, 1s. 2d.; Cocoa Shell, 4d. per lb.

French Chocolates, and that of principal English manufacturers, kept in stock.

61 High Holborn, London, W.C.

FRY'S CARACCAS COCOA, prepared with the celebrated Caraccas Nut.

FRY'S CARACCAS COCOA owes its fine aroma and especial excellence to the Cocoa imported from the Caraccas, so long celebrated for the production of the finest Cocoa in the world and to other choice growths selected for their peculiarly delicious flavour.

FRY'S CARACCAS COCOA will prove to persons in delicate health or under medical treatment a valuable and favourite article of diet.

CARACCATINA,

Registered.

MANUFACTURED BY

DUNN and HEWETT,

is a pure preparation of the

CARACCAS COCOA-NUT,

which, having all

fatty matter extracted, makes it suitable for the most delicate constitutions.

To be had everywhere.

Manufactory, 136 Pentonville road.

Warranted to keep good in any Climate.

ON PAIN AT THE HEART AND IN ITS NEIGHBOURHOOD—CASES AND APHORISMS.

By HORACE DOBELL, M.D.,

Senior Physician to the Royal Hospital for Diseases of the Chest.

BETWEEN a fully developed attack of angina pectoris and an ordinary "pain at the chest" from indigestion, the gradations are almost endless. The varieties in the character, exact seat, direction of extension, duration, collateral symptoms, &c., are extraordinary. The practitioner may well be puzzled in each particular case to set a just value upon the meaning and importance of the pain; and it is no wonder that "pain at the heart" should so often scare the patient, who is sure to have heard of some one who died suddenly with "exactly similar symptoms."

Very early in my medical career I witnessed, and had a great deal to do with, an appalling case of angina pectoris. It made so deep an impression on my mind that, when a student at St. Bartholomew's, I was always looking out for angina pectoris; and long after I began private practice I was haunted by the remembrance of this case, and anxiously watched every patient who complained of "pain at the heart," lest I should, by chance, fail to appreciate the incipient stage of this fearful complaint. As years went on I found that case after case, which I had thought might develop into angina pectoris, got well; that in other cases, attacks of angina would occur when least expected; that exceedingly few of my cases with pain at the heart died; and that, of course, the most interesting were those which eventually recovered; while of those that died it was almost sure to happen, by one chance or another, that no *post-mortem* examination could be obtained. So that, after keeping a watchful note of a case for months or years, with the expectation of one day seeing the explana-

tion of symptoms in the morbid anatomy of parts, the opportunity of doing so very rarely occurred. Yet it appeared to be an object worth a great deal of trouble to attempt to form some practical conclusions as to the meaning of the different varieties of pain at the heart and in its neighbourhood, both with regard to the possibility and prospects of relief or cure, and the means of such relief or cure; and, also, with a view to forming a correct prognosis, and being able to reassure the patient or his friends when needlessly alarmed; or, on the other hand, to warn of approaching danger those who failed to see the appalling import of certain apparently trivial symptoms. I, therefore, continued to keep careful notes of all marked cases of pain at the heart or in its neighbourhood that came before me, whether in private or public practice, taking more and more pains to obtain an accurate description of the seat, direction, and character of the painful sensations, and, whenever possible, watching the patients in their after life. In this way a large number of cases have been carefully collected, which I believe now fairly illustrate nearly all the varieties of pain at the heart. Unfortunately, the number of cases, and the length to which many of them necessarily run, make it impossible to obtain space for them in our medical journals. I shall not attempt, therefore, to give either the full details of cases or to produce my complete series of illustrations of the different forms of pain,—this I must reserve for some future work. In these papers I will confine myself to selecting from a few of the shorter cases such extracts as illustrate some of the aphorisms which have sprung out of my notes, and which appear to be of most interest to the practitioner.

Aphorism 1.—Pain in the region of the heart and down the left arm does not necessarily indicate heart disease.

CASE 1.—Emma E., aged twenty-five, married; ill two years. Violent pain, sometimes aching, but more often pricking, begins under the left breast below the nipple, extends up the left shoulder, down the left arm into the fingers, and leaves a sense of numbness. Sometimes it extends to

the epigastrium, but never to the right side or right shoulder. Some amount of pain is constant, but it is much aggravated by exercise or excitement, and especially by "windy spasms," to which she is very subject. All food produces pain at the epigastrium soon after it is taken. Lying down produces headache and sense of fullness at the chest. Bowels and menstruation regular and normal, urine dark and depositing urates. She thinks she was quite well till a "bilious attack" two years ago; never vomited blood; no rheumatic history; no hereditary disease; heart's dulness normal; action reluctant; sounds sharp; no bruit; sulphate and carbonate of magnesia with bromide of potassium and nitrous ether every morning; effervescing citrate of soda and potash three times a day; abstinence from cheese and malt liquors. At the end of two weeks all symptoms much relieved. A blister to the epigastrium, and a powder of soda, zinger, and saccharated carbonate of iron in water after each meal. At the eighth week the patient was quite well.

CASE 2.—Martha G., aged twenty-five, single; ill three months. Pain at the epigastrium and under left breast directly after food; vomiting of food four hours after it is taken; *when sick the arms become numb*; physical signs normal; anæmic. Powder of soda, calumba, and zinger in water after each meal, alternated with effervescing citrate of soda and potash with hydrocyanic acid and a pill of sulphate of iron, quinine, and aloes, three times a day. At the third week quite well.

CASE 3.—Susan B., aged fifty-three, widow; getting gradually worse six years. Pain just below the left nipple, runs round to left axilla and scapula, *down the left arm, and up the left side of neck*; and the *left hand and arm die up to the elbow*. The pain is usually aching, but exercise brings on a "dreadful pain," always accompanied by a peculiar paralyzed feeling of the left side of the face, and by faintness. She would faint at these times if she did not sit down. Everybody, including her doctor, "who sees her during an attack, thinks she is dying;" eating brings on aggravation of pain; hot drinks relieve it the best; and she gets much relief from retching and vomiting white froth; has not much flatulence; aspect very cachectic; appetite bad; loses flesh; she thinks the complaint was brought on by over fatigue and anxiety during a ten years' illness of her husband. Respiration feeble generally; first sound of heart defective, but no bruit; second sound peculiarly sharp and loud. Abstinence from cheese and malt liquor; powder of soda, zinger, and saccharated carbonate of iron in water after each meal, and a pill of quinine and aloes twice a day. At fifth week all symptoms and signs of illness gone; appetite good.

CASE 4.—Jane C., aged twenty-eight, married; ill four years. Palpitation of the heart, and pain of cutting character under the left breast, producing *numbness of the left shoulder and down the left arm*, and at times down the left leg; right side never affected; when the pain and numbness are bad she becomes hysterical, but does not feel so at first. After eating left side distends, and there is pain below the left scapula; anæmic; flooded before confinement three years ago, and has been weak ever since; but worse since small-pox three months ago; anæmic bruit in jugulars and carotids; heart sounds sharp; no bruit. Dover's powder at night once; powder of soda, zinger, and saccharated carbonate of iron in water after food, alternated with effervescing citrate of potash and soda with bromide of potassium, citrate of iron and valerian. At the eighth week quite well.

CASE 5.—David Y., aged thirty-two, scripture reader; ill a year this time, but was formerly under my care with similar symptoms, from which he quite recovered and remained well many months. Constant pain in the left side, extending from a little below and to the right of left nipple to a little above it, also under left scapula and *down the left arm to the elbow*; also, down the left side of abdomen as far as the sigmoid flexure; never extends to throat. The pain is lingering, dull, aching, and burning; increased by food,

especially cheese; not increased by exercise. It first came in the abdomen, and "worked up;" urine charged with urates; physical signs normal. Abstinence from cheese and malt liquor; compound rhubarb pill, powder of soda, calumba, and zinger in water after meals, alternated with effervescing citrate of potash and soda. At the seventh week quite well in all respects.

CASE 6.—James P., aged thirty-four, clerk; ill three months. Pain and tightness at epigastrium, under left breast and *down the left arm*, in the direction of the ulnar nerve: It comes directly after food, lasts till digestion is over, and then stops; not aggravated by exercise; but worse when sitting still; he sits much. The pain is attended with palpitation of the heart; urine loaded with dark urates; heart easily excited by nervousness; sounds normal. Quite cured in three weeks by powder of soda, calumba, and zinger in water after meals, compound rhubarb pills, more exercise, and abstinence from cheese and malt liquor.

Such cases as these are exceedingly common, and I have a large number recorded, each differing in some of the details, and presenting some special point of interest. But the explanation of nearly all may be comprised under the four following heads:—

1.—A dyspepsia, which in the large majority is characterized by an excess of acidity, and has been long neglected or aggravated by mistaken treatment.

2.—An erratic neuralgia taking its start from the stomach.

3.—An impression on the vaso-motor system of nerves, producing a local interference with circulation. (With regard to this, I agree with Dr. Reynolds, in the remarks made in his paper, read at Oxford, August, 1868. See *British Medical Journal*, Dec. 26, p. 655.)

4.—Deteriorated blood, consequent upon the dyspepsia and other causes, and the effects of this upon nutrition, especially of the nerves and heart.

The readiness with which the cases are cured by diet, regimen, and medicines, directed to the dyspepsia, deteriorated blood and vaso-motor disturbance, testifies to the absence of permanent organic disease. But in Cases 1 and 3 the heart sounds showed that the normal muscular vigour of the systole was beginning to suffer, and hence the pains were aggravated when the heart was *taxed by exercise*. And this indication of threatened organic disease brings us appropriately to a second aphorism, which, notwithstanding such cases as I have instanced, is equally true and important with the first.

Aphorism 2.—The conjunction of pain in the region of the heart and pain in the left arm may be a most important symptom of heart disease, and is never to be disregarded.

This is well illustrated by the following cases:—

(To be continued.)

ON THE ANTAGONISTIC ACTION OF BELLADONNA AND OPIUM.

By BERNARD KAVANAGH, M.D.,

Surgeon to the City of Limerick Infirmary, Consulting Physician to the Lying-in Hospital, and Physician to the City of Limerick Dispensary.

THE following case well illustrates the antagonistic action which is now known to exist between opium and belladonna.

On the evening of the 10th July, Mr. L. called at my house with his two young children, a girl and boy aged respectively three years and nine months, and two and a half years, saying they had taken the belladonna. (It was extract of belladonna, slightly thinned with glycerine, to be applied to the breasts after premature confinement, to suppress lactation.) He and the two servants who accompanied them suffered from all the terror and consternation incidental to such a catastrophe. The

symptoms were as follow :—The girl, who was the elder, and who had taken the larger quantity, laboured under the most frantic excitement, at the same time quite unconscious as to everyone and everything about her, the pupils dilated to the *utmost* extent, the entire skin as red as in scarlatina, though it was only at most an hour and a quarter from the time they took it till I saw them, and the pulse was about 150. The boy was similarly affected, but not altogether so insensible to external objects, not having, as I believe, taken so much of the poison.

I immediately administered five drops of the tincture of opium in the form of enema to the girl, and three drops to the boy, and took them to their own home as quickly as possible, when I applied the stomach pump to both. The fluid pumped from the girl was quite dark, that from the boy not so much so. I pumped some pure water in and again pumped it out until no further trace remained, and set myself to the counteraction of what had been absorbed. I gave five drops more of the tincture to the girl and three to the boy as a small draught; but the excitement caused by giving it was such that I relinquished that mode of doing so, and again had recourse to the enema, which I administered myself with a Maw's syringe, giving five drops in this way to the girl and three to the boy every hour during the night. The violent symptoms continued without any abatement till morning, when about five o'clock both gradually became drowsy, and, soon to my infinite satisfaction, fell into a profound sleep, "a consummation so devoutly to be wished for." I left them at half-past six still sleeping, and, returning at ten o'clock, I found both awake, having slept for some hours. The nurse informed me that the boy was after eating a piece of bread and butter, and the girl recognised her father and me for the first time since the occurrence, and voluntarily stretched her hand to us. The pupils of both had contracted somewhat, but were still very much dilated: the pulse had considerably fallen, being now only 120. Finding them in this satisfactory state I again left, and returned at 4 p.m. when I found them both in their mother's room engaged with their toys and looking as well as ever, having slept a good deal in the interval between my two last visits; the pupils more contracted than at 10 o'clock, but still much dilated beyond the natural size; pulse only 100. Next morning I saw them again, apparently in perfect health, except that the girl was weak and the pupils still slightly dilated. They had both taken light food with a relish, from the time of their recovery, from which time also the redness of the skin had rapidly disappeared. My next visit was two days afterwards, when I found them not only in perfect health, but the pupils quite of the natural size.

This case, like some others which have been recently published, is a good illustration of the opposite effects of opium and belladonna, and though painful and anxious the time spent in administering the antidote, yet, having entire confidence in its efficacy, it was full of interest to me, as it seldom falls to the lot of any medical man to have an opportunity of testing it.

I have no doubt that these children took four times more of the belladonna than would have been sufficient to produce poisonous effects; and when it is borne in mind that at least fifty drops of the tincture were administered to the girl and at least thirty to the boy, and that under other circumstances one would not like to be after giving a quarter that amount to children of their tender age, also its producing none of the effects of opiumism, together with their rapid recovery, *no other remedy having been used*, there can be no further doubt of the fact that these substances are mutually antagonistic of each other.

PROPERTIES OF CURARE.

M.M. Auguste Voisin and Henry Lionville (*Chicago Med. Journal*) have determined that curare is a poison of the motor nerves; that muscular irritability is preserved intact, and that death from curare poisoning occurs only from abolition of motor power in the entire economy.

OBSERVATIONS ON THE ARRANGEMENT OF THE REFLECTIONS OF THE PERITONEUM.

By ALEXANDER MACALISTER,
Demonstrator of Anatomy Royal College of Surgeons.

IN collating the descriptions of the peritoneum in our various manuals and works of anatomy, a considerable discrepancy will be found in the account of the formation of the transverse mesocolon: the majority of authors, as Gray; Harrison, Cloquet, Ellis, Blandin, Marjolin, Pittard (Todd's Cyclopædia), Portal, Jamain, Blancard, Bartholinus, Froriep, Vesalius, Glisson, Fabricius ab Aquapendente, Spigelius, Lauth, &c., holding the view that this transverse fold is the direct continuation backward of the two ascending layers of the great omentum which separate to enclose the arch of the colon, and then, re-uniting and passing back to the spine, constitute the true transverse mesocolon; others, as Luschka, Huschke, J. F. Meckel, Müller, Hansen, Allen Thomson, and Holden, advocate the view which originated with Haller, that the mesocolon is distinct from the omentum, and formed by a simple duplicature of the single layer of peritoneum, descending from the spinal termination of the great omentum.

Attention has been also directed to this point recently, by a notice favourable to this theory in the last edition of "Quain's Anatomy," and by a paper on an anomalous arrangement of the peritoneum, by Dr. Chiene, Demonstrator of Anatomy in the University of Edinburgh ("Journal of Anatomy and Physiology," vol. ii. p. 13, et seq.), in which this latter view is advocated from the arrangement found in a subject in which, probably from intra-uterine peritonitis, the usual changes in position had not taken place in the course of the development of the different parts of the intestinal tube, and, as a consequence, the transverse mesocolon had not contracted an indivisible adhesion with the recurrent layers of the omentum. The subject is also referred to by Professor Cleland, of Galway, in a paper in the same Journal (vol. ii. p. 201), and from some observations which are also based upon a specimen of abnormal arrangement of this portion of the peritoneum, he deduces the conclusion, that the statement that at a certain period of development there is a mesocolon quite unconnected with the walls of the sac of the great omentum, is true with regard to the sigmoid flexure descending colon, and precisely one half of the transverse colon; but that for the right half of the transverse colon, the peritoneal lamina derived from the pyloric ends of the stomach is directly continuous with the investment of the colon. Adhesions, he likewise remarks, are, as far as at present known, the result of pathological changes.

The opinions on this subject thus resolve themselves into three:—1st, That the mesocolon is the direct continuation of the recurrent layers of the omentum, which separate to enclose the colon. 2nd, That the mesocolon is separate from the omentum, and continuous with its descending layer alone. And, 3rd, That the mesocolon is partly (on the left) separate from, and partly (on the right) formed by the ascending layers of the great omentum.

Now, in order to determine which of these theories of formation is correct, there are three tests applicable. The first is that of comparative anatomy, the second is embryology, the third is that derived from the various forms of anomalous arrangements of this part of the peritoneum. And I purpose making a few remarks on these points, as applied to the elucidation of peritoneal development.

1st. With reference to comparative anatomy.—My attention was recently called to this subject of peritoneal arrangement forcibly on dissecting a Badger (*Moles tarus*). On opening the cavity of the abdomen, I found the upper part of the peritoneum arranged as usual, as far as the serous investment of the stomach and spleen, from the lower margin of both of which the great omentum descended.

The peritoneum forming this fold did not project farther to the right side than the pylorus, and from that point to the right, the serous lamina forming the meso-duodenum, which was large and moderately loose, did not pass to the omentum at all, but surrounding the duodenum, passing backwards and then continuing outwards along the middle colic branches of the superior mesenteric artery, formed a right of the transverse mesocolon. The descending layers from the convexity of the stomach passed downwards, and formed a large omental sac, whose cavity was distinct. The recurrent layers passing back to the spine, met the pancreas and clothed it on its anterior, upper and lower aspects, surrounding it for more than two-thirds. The two layers here separated, the one continuous with the lamina involuted through the foramen of Winslow, ascended resting on the aorta, and was arranged as usual, not extending quite as far to the right as it commonly does, the descending lamina covered the left kidney on the left side, and in the middle and on the right, passes along the colic vessels to enclose the colon, forming the transverse mesocolon. This fold was continuous with the left lumbar mesocolon, and on the right with the right mesocolon, which was loose, and allowed the colon a considerable range of mobility. The mesocolon was joined thus of a single layer passing from the spine surrounding the intestine, and passing back to impinge on the spine prior to its contributing to the formation of the mesentery.

From this dissection it is at once clear that the theory of Haller, Luschka, &c., is borne out in this animal at least; and when the peritoneal arrangement of the Porpoise or *Balænoptera* among the Cetaceas is compared with this, the formation of the mesocolon will be found to be precisely similar.

The same method of arrangement occurs in the Armadillo, Mole, Tiger, and Lion, in all of which the recurrent layers of the omentum ascend to and separate at the pancreas, the involuted or proper omental layer ascending, while the inferior or continued lamina forms, by passing along the middle colic vessels, the transverse mesocolon. John Hunter, although he does not seem to have supported any particular theory of the formation of the mesocolon, notices in most of his dissections how the layers of the epiploon terminate posteriorly; and in his "Essays and Observations" (vol. ii.) he describes the omentum as descending to the colon, and adhering to it in the Pig, Horse, Tapir, and Hare (in the latter animal, however, it is not attached at its left extremity, according to my observations); partly adhering (on the right side) and free on the left and adherent to the pancreas in *Macacus silenus*, *Cynocephalus porcarius*, *Cebus apella*, *Papio maimon*, and *Lemur mongoz*; and this arrangement I have confirmed in many quadrumanous animals which I have dissected, as *Macacus nemestrinus*, and *Siniens*, *Cercocebus fuliginosus*, and *Cercotheus ruber*. Leaving these comparatively few animals out of account, in the vast majority of mammals the arrangement is certainly in accordance with the theory of Luschka and Haller. Thus, Hunter notices that in *Jacchus vulgaris* the epiploon adheres to the great curvature of the stomach, and to the root of the mesentery, but not at all to the colon. He also notices the arrangement alluded to above in the Lion and Tiger, and describes a similar disposition in the Leopard, Dog, Zibetha, and Civet (*Viverra*, *Zibetha*, and *Civetta*), *Rhizæna tetradactyla*, Otter, Skunk (*Mephitis chinche*), *Ratelus mellivorus*, Seal, Sloth, both *Cholepus* and *Bradypus*, Armadillo, Anteater, Agouti, Marmot, Gray Squirrel, Paca, Phalanger, Opossum (*Didelphys virginiana*). These may thus be taken as the representatives of the entire orders—Carnivora, Edentata, Cetacea, and in part of Rodentia, Marsupalia, and Quadrumana. Some of these and their allies, as the Otter, Seal, and Opossum, Dog, Sloth, Armadillo, Porcupine, Hedgehog, and Mole, I have verified for myself; and for the others, the description given by Hunter is, contrary to his usual obscure style, clear and explicit. The deduction from comparative anatomy is thus easily traced, for if all animals be developed upon the same type, it is manifest

that while the theory of Luschka, Meckel, and Haller, accounts for both the appearances from adhesion, and those from separation of the omentum and mesocolon, the older theory cannot account for the two separate plans of extension noticed in the above brief sketch of the mammalia; cases of adhesion do not invalidate the former theory, but one case of separation, if we acknowledge a common typical development, is fatal to the latter theory.

Having followed this method of evolution by tracing the omentum in the mammalian class of the animal kingdom, we shall, in the second place, trace the evolution of the omentum and mesocolon, in the life history of a single animal, by examining the peritoneum in its fetal conditions in the human embryo. In its primitive and simplest appearance of development, the peritoneal membrane appears as a differentiated parablasic lamina derived from the ectoblastoderm, lining the common body cavity. No appearance of a great omentum can be perceived in the human embryo during the first month, but about the eighth week, a little fold of peritoneum projects from the greater curvature of the stomach. This has been very accurately and carefully delineated by Johann Müller (Meckel's Archiv. 1830, p. 395, pl. xi.) and by Meckel (*ibid.* vol. iii.). This projecting fold is distinctly made by the two layers of peritoneum, which have invested the stomach, uniting along its great curve, passing down for a short distance, then turning backwards not upwards, and impinging on the spine, sends its lower layer out as the upper lamina of the transverse mesocolon. Before this fold is visible as an actual descending layer, that is, about the seventh week, the omental or involuted layer does not descend below the level of the stomach; and hence the continuity of the mesocolon with the anterior layer alone is very clearly apparent. As this internal layer, *i.e.*, the true sac of the omentum, enlarges and descends, it pushes before it the fold descending from the stomach and extends it into a pouch. The adhesion, however, between the root of the mesocolon and the spine is, however, not displaced by this growth; and so the omentum, which at first lay above, and not even in contact with the transverse colon, gradually extends in front of it and overlaps it, becoming pendent anteriorly. It is thus to be seen that until the stomach assumes its transverse position, no trace of an omentum is visible, and that the transverse mesocolon is really formed from that portion of the mesogastrium which is carried by the colon in the course of its transit across the spine, from the left side to the right iliac fossa.

In an embryo of barely three inches length, in which the cæcum was still in a condition of transition, having only arrived at the upper part of the right lumbar region, the peritoneal relations were clear and unequivocal. The lesser omentum was extremely short, and the spleen was by peritoneum closely tied to the left extremity of the stomach. From the convex margin of the stomach, a short great omentum descended for about two lines, turned up on itself, and was distinctly traceable back to the spine from whence its inferior lamina passed out, forming a separate mesocolon for the entire length of the transverse colon. On the right side, the meso-duodenum was distinct, and surrounded this organ, after which it was continued forwards to surround the right or hepatic angle of the colon, and this was in a downward direction, continuous with the right lumbar mesocolon; thus, in this embryo, which was probably about the tenth week of development, a perfect and definite separation between the layers was traceable.

A still more distinctive and characteristic arrangement I met with in another foetus, about $4\frac{1}{2}$ inches in length, probably about the end of the third month in age. In this, the viscera were more nearly in their normal states of arrangement, the great omentum, distinct and descending for about a quarter of an inch on the right, and four lines on the left; after a short course it turned up, and was traceable above the level of the transverse colon, where it united with the transverse mesocolon. On the left side, the adhesion or union was extremely indistinct, and takes place only at the spine, in fact, the arrangement was as

described by Professor Cleland; but from this side over to the right, there was no sudden alteration, but a gradual extension colon-wards of the union of the two layers of peritoneum, so that the adult condition, so clearly and evidently *not* present in the former embryo, was established at a *point* immediately to the left of the hepatic angle of the colon; but from this point, on tracing the mesocolon to the left, a gradual recedence of the adhesion took place, so that on pulling down the colon, and reflecting upwards the free edge of the omentum, the line of amalgamation was seen to trend upwards, and to the left from the colon to the spine. This condition has been referred to by Müller, and he figures a diagrammatic section (pl. xi. fig. 8) of a partial union of the mesocolon and omentum, extending for half way in these folds.

In dissecting an adult female subject within the past month, the condition of adhesion was perfect as far as the splenic flexure, and although the bag of the omentum was normal, yet no dissection could separate the mesocolon from the omentum, even at the left side. Now I conceive, that in this case, and it is one of very common occurrence, we have the condition which Professor Cleland regards as only the result of pathological change.

So far does the embryological evidence coinciding with that from comparative anatomy bear out the same theory of peritoneal arrangement, and it only remains for us to notice briefly some of the anomalies of arrangement which may throw light upon this subject. The anomaly described by Dr. Chiene (loc. cit. p. 14) is a permanent state of the original embryonic separation of the two laminae, attended with a displacement of the duodenum and cæcum. That described by Professor Cleland was probably one of partial adhesion; in fact, a permanent condition of the fetal state resembling that of Müller's fig. 7, with some varieties in the position of the intestinal folds which masks its arrangement.

Three kinds of anomalies have fallen under my notice, —1st, that of a very short omentum, in which the descending layer, when extended, scarcely covered the transverse mesocolon, but with the usual attachments. 2nd, A partial want of union at the left side, giving the peritoneal arrangement noticed by Professor Cleland. 3rd, A complete obliteration of the cavity of the omentum, without any traces of inflammation, a condition dependent on an increase in the adhesion power of the laminae affecting the two contiguous internal surfaces of the sac.

IDIOPATHIC TETANUS.

By FRANCIS E. CLARKE, M.B., T.C.D., M.R.C.S. Eng.

SEEING an article in the MEDICAL PRESS AND CIRCULAR of June 3rd, regarding the treatment of tetanus, founded on two cases brought under the consideration of the Surgical Society, and recognizing the importance of every interesting case of the kind being made public, I am led to communicate the following, which I shall endeavour to make as brief as possible:—

M. A. W., a little girl, aged twelve years, was first seen by me in company with Dr. Clarke, of Dunfanaghy, Co. Donegal, on December 28th last, at the request of her father, who is in extremely poor circumstances. Her mother has been dead some years, and consequently, she has not received proper care. She resides in a wretched cabin in one of the most exposed and mountainous districts along the northern coast of Ireland. The week preceding this had been excessively cold and wet, and to this inclement weather she had been much exposed, and for the last two days had become the subject of fits. During these there were complete rigidity of the muscles of the back and lower limbs, opisthotonos, and slight tendency to trismus. She suffered no pain or rigidity during the intervals, but appeared extremely low and depressed. Pulse small, rapid, and weak; tongue dry, bowels costive, great tendency to yawn; slight pain in the lumbar region;

dilatation of both pupils, and suffused conjunctivæ. A full dose of turpentine was ordered, which was to be repeated in the evening, and castor oil on the following morning.

26th.—Worse; countenance has assumed a most uneasy, apprehensive aspect. The paroxysms very frequent during the day until evening, when eight minims of tincture of Indian hemp were administered, by which sleep was induced, only one spasm occurring during the night.

30th.—She complains of vertigo and of her vision being greatly affected. The pupils still largely dilated; spasms neither as frequent or severe. Pain in the lumbar region being worse a blister was applied.

31st.—Paroxysms more frequent; pupils, if anything, more dilated. A mixture containing four-drop doses of tinct. cannab. Indic. with cherry-laurel water was ordered to be given at intervals of three hours if spasms continued.

January 1st, 1869.—Better; unpleasant symptoms of the drug again complained of. It was ordered to be discontinued except at bedtime.

From this date no change perceptible for some days. Indian hemp appeared gradually to lose its control; and the patient's great intolerance to it precluded the dose being increased. The extreme torpidity of the bowels was constantly relieved by calomel.

13th.—Trismus now present in increased intensity and spastic rigidity quite apparent during the intervals in the muscles of the back of the neck. Indian hemp again given; galvanism tried, but without any appreciable result.

18th.—Worse; breathing, although hurried, is laboured and accomplished with difficulty; opisthotonos; trismus; risus sardonius now visible; extreme dilatation of both pupils; the irides appearing as mere rings scarcely visible; body greatly emaciated, and diarrhœa; ordered chalk and opium powder and Indian hemp.

20th.—Much worse; no sleep; frequent paroxysms; trismus so permanent that liquids could with difficulty be taken. Ordered half a grain of opium at night.

21st.—Still worse; although the paroxysms are less frequent the urgent symptoms continue; dyspnoea; dysphagia; hiccough; stupor combined with insomnia; dilated pupils; labouring heart; meteorism and rigidity of the abdominal muscles. Ordered turpentine enema; linseed poultices to abdomen, and wine.

22nd.—Trismus again extremely alarming. Calomel was now given, and mercurial ointment rubbed into axillæ and over spine; assafœtida and opium injections.

23rd.—No improvement; mercury assiduously persevered with.

25th.—Much better; salivated. From this day the paroxysms gradually diminished in frequency, assafœtida injections occasionally being given and mercury kept up.

31st.—Nearly quite well. A paroxysm occurred in the morning, which proved to be the last.

The duration of this case is most interesting, lasting, as it did, thirty-six days, which, even for the idiopathic form, is much longer than usual.

Rigidity of the muscles during the intervals not being apparent, at all events for the first fortnight, appears singular, the late Professor Colles, in his "Surgical Lectures," having laid it down as a rule that this spastic rigidity is the diagnostic mark of tetanus in general. The extreme and permanent dilatation of the pupil was most remarkable, even opium having little control over it. This drug is generally contra-indicated by the received pathology of tetanus, as tending to increase polarity and congestion of the spinal cord; but considering this dilatation of the pupils probably caused by some irritation of the sympathetic, leads me to suppose the possibility of there being a slightly contracted state of the blood vessels of the cord from the same source. Were this the case opium would be indicated rather than the reverse. But, on the other hand, is increased polar excitement and diminished afflux of blood at all compatible? Even frogs have been made tetanic by the administration of opium causing con-

gestion of the cord; and Mr. Lockhart Clarke says he has detected inflammatory symptoms by *post-mortem* examination, although autopsies until lately were said not to reveal anything. Secondly, is a dilated state of the pupils invariably present?

Cannabis Indica at first produced a most salutary effect, but subsequently appeared to lose its influence. The extreme intolerance which the child had to it, and indeed to all narcotics, rendered larger doses hazardous; but, did this peculiar idiosyncrasy not exist, I feel certain that Indian hemp persisted in, and given in gradually increased doses, would be found a most valuable remedy.

The patient certainly recovered whilst under the influence of mercury, but whether it conduced to such I cannot determine.

As to the recurrence of the symptoms, the jaws were not first affected, as is usual in traumatic tetanus.

I regret that ice to the spine or nicotine could not have been tried; but the wretched circumstances of the patient and want of proper nursing precluded any treatment requiring either energy or intelligence.

South Molton, Devonshire: July, 1869.

ON THE CAUSATIVE AGENCY OF THE SKIN AND LIVER IN THE INDUCTION OF PHTHISIS AND OTHER SCROFULOUS MALADIES.

By FRANCIS M. LUTHER, M.D., Cappoquin.

THE blood is alkaline; the sudoriparous glands remove acids from it as fast as they are generated, the process being mainly one of simple transudation. Liebig states that the alkalinity of the blood aids, in a remarkable manner, the oxydation and combustion of grape sugar; it also aids the solution of oxides of iron. To it is due the extreme facility with which the blood moves through the minutest vessels, the delicate coats of which are impermeable, or very nearly so, to alkaline fluids. The free alkali acts as a resistance to many causes which, in its absence, would coagulate the albumen (see "Carpenter's Physiology," p. 83).

An acid state of the blood, therefore, prevents the oxydation of liver sugar by the lungs, hinders the absorption of iron into the blood, favours congestion and the deposition of lymph and transudation from the blood-vessels. Now, the blood has been proved to be acid in diabetes, and diabetes usually terminates in phthisis. It is possible that the acidity of the blood and the glycohemina which are constantly operating in diabetes, may occasionally occur in incipient phthisis. It has, indeed, been asserted by competent observers, that glycosuria always precedes phthisis; and phthisis prevails in countries subject to variation of temperature, where, from frequently-obstructed perspirations, the blood must be often acid. Glycohemina frequently causes anthrax, also spontaneous mortification of the toes. Virchow, of Berlin, denies that tubercle is a product *sui generis*. He implies that it is a normal tissue undergoing retrograde metamorphosis. If, as has been asserted, glycohemina always precedes phthisis, why do we not have the phenomena of diabetes—viz., excessive thirst, insatiable appetite, and diuresis? I answer, because the system is not saturated with the poison as it is in diabetes. How many glasses of alcohol will not a tippler drink before the false appetite and the thirst for cold water, so well known to such persons, supervene? Probably, if attention were directed to the subject, some diuresis might be noticed; but the lung may be equal to the task of elimination, and yet be materially injured by the presence in its capillaries of saccharated blood. A degree of uremia, not sufficient to attract notice, by the induction of dropsy or any of the more marked symptoms of kidney disease, may cause serious structural change in the arteries, heart disease, or aneurism. Again, I am almost certain that congestion of

the portal system and liver precede the development of phthisis; and it is well known that fatty degeneration of the liver is discoverable after death in a vast majority of phthisical cases, and in a few other diseases, unless Bright's disease. This fatty degeneration of the liver is not found in cases of hydrothorax or hepatized lung, so that it cannot be due to its being overtaken in excretion of hydrocarbon. The congestion of the liver, which I presume to exist, impedes the secretion of bile (the bowels, in the early stages of consumption, are usually constipated, unless when there is diarrhoea, both results of different degrees of congestion); it hinders, or perverts, the manufacture of liver fat, possibly making a fat unfitted for being deposited in the cellular adipose tissue, or aiding in cytogenesis calorification, &c. Emaciation is a very early symptom in phthisis, and other tubercular diseases, and yet, strange to say, the blood is found to be loaded with fat in tuberculosis. In healthy blood the fat exists only in a saponified state; but when the blood is acid, it cannot be saponified. It is right, however, to state that this accumulation of fat in blood was also noticed in Bright's disease, nephritis, diabetes, chronic diseases of the liver, dropsy, jaundice, mammary abscess, and pneumonia. In the first three we may presume the blood to be acid; in the liver diseases congestion, of course, existed; in that of mammary abscess the fat, which should have been eliminated with the milk, was thrown back on the blood. Now, as regards the "lædentia" and "juvantia," dandelion is very much estimated in the country in the treatment of consumption; and Astley Cooper treated all scrofulous diseases with different mercurials and alkalies—hydrargyrum cum creta, oxy-muriate of mercury, carbonate of soda, and liquor potassæ. Again, Coulson, in his work on the hip-joint, says:—"The organ most frequently found deranged is the liver; and at the infirmary leeches and other local means are applied to this organ oftener than to the affected joint." Water on the brain is believed to be a scrofulous affection; in it the action of the liver is undoubtedly perverted, and the appetite is frequently abnormal, like that of a diabetic patient. Now, calomel and diuretics are more beneficial in this malady than any other remedies, restoring the tone of the liver, and, perhaps, assisting the kidneys to eliminate sugar.

I doubt extremely if the mercury acts in this disease as an antiphlogistic; at all events, salivation is seldom produced, and is not necessary. But it may be said that salivation is very injurious in scrofula. I grant that; but salivation produces excessive congestion of the portal system (the very object we desire to avoid), as is evinced by the colics and dysentery which form a distressing symptom of it. The analogy existing between typhoid fever and consumption, and the prejudice which exists on the Continent that the latter disease is contagious, is worthy of notice, but is, however, foreign to this subject.

I would strongly urge the use of the Turkish bath in phthisis and other tubercular diseases, with the double object of exciting the functions of the skin, and relieving the congestion of the abdominal viscera.

(Published with the Transactions of the Cork Medico-Chirurgical Society: Dub. Quart. Journ. of Med. Science.)

Further Observations.—In order to counteract the acidity of the blood (which I suppose to exist in phthisis, and to be a powerful factor in the production of tubercle) I would subject the patient, after the Turkish bath, to alkaline douches or immersion; and, with a view of relieving the engorgement of the portal system and chylipoietic viscera, I would exhibit frequent emetics and cholagogues, while cupping and blistering the liver rather than the lungs. Therapeutics consists of subtraction, addition, and proportion. Eliminate here, pour in there, and preserve due harmony of action in all organs.

Still, while suggesting (to such as can follow up the ideas thrown out) a course of treatment for phthisis and

scrofula, I think one ought not to abandon the hope that a specific may exist, and, if so, be found, for those direful maladies. That excellent practical physician, Thomas Sydenham, did not doubt but that many such remedies existed in Nature. He was of opinion that they were to be sought in the vegetable kingdom, and that, since Nature makes little or no effort to throw off chronic diseases, at least none so certain as to afford useful indications for treatment, specific or antidotal remedies were to be sought for such cases. What method, save empiricism alone, should guide our search after a specific, I cannot, however, fancy, since the word means a remedy whose mode of action we cannot explain, and one, therefore, which theory cannot aid us to find.

Since science, however, is so very imperfect, and so unproductive of curative results, experiments should be made with various medicines, some one or other of which may come to deserve the proud title of remedy for those hitherto incurable maladies.

I wonder the exhibition of lemon juice has never been tried in phthisis. It would be an interesting experiment to administer a course of it to a number of hospital patients simultaneously. I purpose trying it in the next case of well-marked phthisis that comes under my notice. It is a question whether the victories over disease won by science much exceed in number or importance those gained by empiricism.

Perhaps some day tubercular deposits in the lungs may be discussed by electrolysis, as they have been in glandular tumours.

ON EXTENSION IN FRACTURES OF THE THIGH BY MEANS OF A WEIGHT AND PULLEY, INCLUDING A SUGGESTION OF THE WEIGHT AS A MODE OF PRODUCING COMPRESSION IN ANEURISM.

By HENRY THOMPSON, M.D.,
Surgeon to Tyrone Infirmary.

SHOULD Mr. Stapleton have succeeded in treating fractures of the femur successfully, keeping up the extension as long as required by the above method, he decidedly deserves credit; but as to the originality of the plan, to that he has no claim, for I distinctly recollect it having been used under Mr. Cusack's direction very nearly, if not quite, forty years ago in Steevens's Hospital. It was not the usual practice, but only adopted in oblique fractures and other cases, in which there was unusual difficulty in keeping up the necessary extension, and these cases were very few.

As well as I recollect, it was an extremely irksome and unbearable mode of effecting the purpose, and on that account generally very soon given up, and only resorted to when other means failed. If Mr. Stapleton has deprived it of those objections he is entitled to as much credit as if he had originated it.

So much for the use of a weight to keep up extension. The weight has also been used for the purpose of keeping up pressure, where that is called for, as in aneurism and some other diseases; but I do not know that the following plan of adapting it to the production of elastic pressure in the former disease has as yet been described. It occurred to me to try it in a case in which no other apparatus could be endured, and in which by its means the pressure could be maintained for any length of time.

The patient, affected with popliteal aneurism, was placed on the pelvic cushion of Read's or Carte's compressor; to the side of this, which was farthest from the diseased vessel, was fixed a loop of strong India-rubber, just large enough to admit the end of a thin deal lath, which passed across the front of the body and projected about a foot over the side of the bed at the diseased side. In this lath, where it passed over the part of the artery to be compressed, was cut a square mortice, through which passed the stem of the compressing pad, and over

the top of this stem another strong band of India-rubber; the projecting end of the lath was furnished with several notches about half an inch asunder, and from one of these was suspended a half-pound weight. Thus we had an elastic loop confining the fixed end of the lath, an elastic band acting directly on the compressing pad, and the high elasticity of the lath itself, combining as much elasticity as could well be brought to bear, and at the same time admitting of any amount of pressure, by increasing the weight or moving it from notch to notch so as to lengthen, and of course increase the power of, the lever by each move—this the patient could do for himself—and, by changing the position of the weight occasionally, gave himself so much relief without interfering with the compression of the vessel, that he was able to bear it longer than by any other plan, including digital, by relays of assistants, that I ever saw used.

On this principle a very handsome instrument could be constructed, substituting a steel bar for the lath and furnish a polished cradle to keep off the bedclothes, &c.; but the one I used, extemporized for the occasion, with a needle, some strong thread, and a penknife, answered the purpose well, and has the advantage of being accessible to every one.

Our Analytical Department.

MUSTARD.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

(Continued from page 100.)

1st Sample.—FINCH, RICKMAN, & Co.'s MUSTARD (FINE).
Messrs. Finch, Rickman, & Co., London.

"Manufactured from the finest seeds, and guaranteed free from anything injurious."

Ash 2.5 per cent.—*Largely adulterated with wheat flour, and coloured with turmeric.*

2nd Sample.—COLEMAN'S MUSTARD (SUPERFINE).
Messrs. J. & J. Coleman, 108, Cannon-street, London.

"Manufacturers to the Queen, the Emperor of the French, and the Prince of Wales. Highest award for mustards, London 1862, Paris 1867, Dublin 1865."

Three per cent. of a nearly white ash, slightly coloured with turmeric.—*Mixed with small amount of wheat flour, and coloured with turmeric.*

3rd Sample.—COLEMAN'S MUSTARD (FINE).
White ash 3 per cent. More largely coloured with turmeric than the second sample.—*Mixed with a large quantity of wheat flour, and coloured with turmeric.*

4th Sample.—COLEMAN'S MUSTARD (GENUINE).
This mustard contained no turmeric or other foreign substance, and gave 4½ per cent. of a greyish ash.—*Genuine.*

5th Sample.—KEEN'S MUSTARD (FINE QUALITY).
Messrs. Keen, Robinson, Bellville, & Co.
"First manufacturers in London," "1742;" "Parveyor to the Prince of Wales."

This mustard gave 4 per cent. of an ash, which was nearly white. Contained wheat flour and a small quantity of turmeric.—*Adulterated with flour and coloured with turmeric.*

6th Sample.—SADLER'S GENUINE DURHAM MUSTARD.

"Manufactured expressly for Phythian from the finest seeds, and warranted genuine."

This mustard gave rather a high percentage of ash—viz, 5.5 per cent.—but appeared genuine. It was not coloured with turmeric.—*Genuine.*

7th Sample.—COLEMAN'S MUSTARD (DOUBLE SUPERFINE).

This specimen of mustard gave 4 per cent. of a white ash. It contained turmeric and rather a large proportion of wheat flour.—*Adulterated with flour and coloured with turmeric.*

8th Sample.—TAYLOR BROTHERS' MUSTARD (SUPERFINE).

"The challenge, purity, pungency, and flavour."

Messrs. Taylor Brothers, London.

This mustard gave 5 per cent. of ash, and was strongly fluorescent. It contained a considerable quantity of wheat flour.—*Adulterated with flour, and strongly coloured with turmeric.*

9th Sample.—SADLER'S CELEBRATED OLD ENGLISH MUSTARD (DOUBLE SUPERFINE).

Messrs. Sadler & Co., Southwark, London.

"Manufactured more than a century. Prepared from the finest seeds."

This mustard gave about 4½ per cent. of white ash. It contained wheat flour, and was coloured with turmeric.—*Adulterated with flour, and coloured with turmeric.*

10th Sample.—KEEN'S MUSTARD (SUPERFINE QUALITY).

This sample gave 4 per cent. of ash, which was nearly white, and contained wheat flour and turmeric.—*Adulterated with flour, and coloured with turmeric.*

11th Sample.—TAYLOR BROTHERS' MUSTARD (DOUBLE SUPERFINE).

This mustard gave 3 per cent. of ash, and seemed to contain rather a large amount of wheat flour. Coloured with turmeric.—*Adulterated with flour, and coloured with turmeric.*

12th Sample.—KEEN'S GENUINE MUSTARD.

This mustard gave about 4 per cent. of ash, nearly white. This sample seems, in every respect, pure.—*Genuine.*

13th Sample.—KEEN'S MUSTARD (DOUBLE SUPERFINE).

Ash 4 per cent. Was coloured with turmeric, and contained wheat flour.—*Adulterated with flour, and coloured with turmeric.*

14th Sample.—FINCH, RICKMAN, & Co.'s MUSTARD (SUPERFINE).

This mustard gave 3 per cent. of ash; it also gave but a small amount of fluorescence, but contained wheat flour.—*Adulterated with flour, and slightly coloured with turmeric.*

15th Sample.—GENUINE MUSTARD (DOUBLE SUPERFINE).

Messrs. Finch, Rickman, & Co., London.

This mustard gave about 5 per cent. of ash, nearly colourless. It contained no turmeric, and was, in every respect, a genuine sample of mustard.—*Genuine.*

16th Sample.—MUSTARD (DOUBLE SUPERFINE).

Manufactured by Finch, Rickman, & Co., London.

Gave 3 per cent. of ash fluorescent, and contained wheat flour.—*Coloured with turmeric, and adulterated with wheat flour.*

17th Sample.—SUPERFINE DURHAM MUSTARD.

This mustard exhibited considerable fluorescence. The ash was rather coloured, and amounted to 5 per cent.; it contained wheat flour.—*Adulterated with flour, and strongly coloured with turmeric.*

18th Sample.—TAYLOR BROTHERS' MUSTARD (FINE).

This mustard was adulterated with wheat flour and pepper, and exhibited considerable fluorescence. The ash was 5 per cent.; the fluorescence was considerable.—*Adulterated with flour and pepper, and coloured with turmeric.*

19th Sample.—FINE DURHAM MUSTARD.

Messrs. Sadler & Co., Southwark, London.

Contains wheat flour, and fluorescent. Ash 4 per cent.—*Adulterated with flour, and coloured with turmeric.*

20th Sample.—TAYLOR BROTHERS' GENUINE MUSTARD.

"Dr. Hassall, in his Report, says:—'I find Taylor Brothers' genuine mustard to consist entirely of the flour of mustard seed of superior quality, delicate flavour, and much pungency."

"(Signed) ARTHUR HILL HASSALL, M.D."

Alcoholic solution; not fluorescent. Ash 4 per cent., and in every other respect genuine.—*Genuine.*

21st Sample.—SHELLEY'S MUSTARD (DOUBLE SUPERFINE).

Messrs. Shelley & Co., Dublin.

Alcoholic solution; fluorescent; contains capsicums. Ash 7 per cent., the excess of which consisted of sulphate of calcium; it also contained wheat flour.—*Adulterated with flour, sulphate of lime, and pepper; and coloured with turmeric.*

22nd Sample.—CHERRY'S MUSTARD (BROWN).

Dublin.

This mustard was hardly fluorescent at all, but exhibited a trace. The ash was 11 per cent., the excess of which appears to be gypsum, or plaster of Paris. It contained wheat flour.—*Adulterated with flour and sulphate of lime.*

23rd Sample.—SHELLEY'S MUSTARD (BROWN).

Messrs. Shelley & Co., Dublin.

This mustard, like sample 22, contained no turmeric, or, if present, a very minute trace. The ash was, however, 11 per cent., about half of which is sulphate of calcium. Contained capsicums.—*Adulterated with capsicums, flour, and plaster of Paris.*

24th Sample.—ARMISTEADS' MUSTARD (GENUINE BROWN).

Messrs. Armisteads & Co., London and Leeds.

"Established 1748; unrivalled for purity, strength, and flavour; tried upwards of a century, and universally approved, being prepared by a peculiar process ensuring the full strength and flavour of the seed."

The alcoholic solution of this mustard exhibited considerable fluorescence. It also gave a very large ash, 13 per cent., about 9 of which consisted of sulphate of lime; it also contained pepper.—*Adulterated with sulphate of lime and pepper.*

25th Sample.—COMMON MUSTARD (SECONDS).

Maker unknown; retailed at 6d. per lb.

Ash 3 per cent. The tincture exhibited strong fluorescence, and when examined by the microscope it was seen to consist almost entirely of wheat flour; it also contained pepper.—*Largely coloured with turmeric, and adulterated with flour.*

26th Sample.—COONEY'S GENUINE BROWN MUSTARD.

Messrs. C. Cooney & Co., Dublin.

Contained turmeric, and gave 13.5 per cent. of ash, the excess of which consists of sulphate of calcium.

It will be seen from the above Report that almost the universal adulterant is wheat flour. "White struck" is the technical term by which the manufacturers know this substance universally used by them. It is the finest wheaten flour, slightly coloured with turmeric (about one pound to the ton*) (? cwt.). It will be seen from our Report that "white struck" is used in all the mustards except those labelled "genuine," and even some of these; generally, however, those so branded, on examination, proved to be really genuine articles. From a sanitary point of view, there may not be much harm in the substitution of a certain percentage of flour for mustard; but on the public such a substitution is illegal and a fraud; and to the class of purchasers who are able to buy their mustard in the original package, we say: buy your mustard, and, if you wish to get mustard not struck, see that the canister has the name of a respectable manufacturer upon it, and that it is

branded genuine. Such an extra superlative soubriquet as "double superfine" no longer expresses, as the people imagine, the fineness of the mustard, but only that the manufacturer put in but a limited amount of "struck." How is the poor man, who pays his 1d. or 1½d., to know what he gets? Sample 25 is a fair specimen of the character of mustard that he gets—we are afraid, in some instances, much worse; and he pays frequently a very high rate per pound for the rubbish (retail at 1d. per ounce, or 1s. 4d. per pound, by the huckster). Sample 25, if sold, would be retailed by any respectable house for 6d. per pound; the manufacturer gets about 3½d. We can well imagine what this can be at the present price of mustard seeds.

The proportion of struck is generally as follows:—
Genuine.—All mustard; retailed at 2s. per pound.

Double superfine is the mustard most in demand, and consists of about 5 per cent. of "struck;" is retailed at 1s. 8d.

Superfine consists of 10 to 12½ per cent. of struck, and is retailed at 1s. 4d. per pound.

"Fine" is about the same, only that the mustard is not sifted through so fine a sieve.

The husks, or "hulls," as they are technically termed, are the particles of epidermis of the seeds. The different qualities of mustard are sifted through different qualities of silk sieves. The finer the quality of silk, the less of this "hull" passes through; hence the common qualities are much darker on account of this "hull." As regards the manufacturers, we will do them justice to say that we believe that many of them have no larger profits upon the low-class mustards than upon the genuine; but it makes it none the less an adulteration. The other adulterants are what may be termed accompaniments. The flour is the lie that brings many others. As the quantity of flour is increased, it becomes necessary to add turmeric; if it were not for this, it would, by its pale complexion, tell its own tale. Pepper, for the same reason, is added to compensate for the want of pungency found in the flour. The pungency of pepper is, however, quite distinct from that of mustard, which produces no permanent heat in the mouth.

A more serious adulteration is sulphate of lime, or plaster of Paris. This is probably used to facilitate the dressing of the mustard. In some cases the quantity of sulphate of lime present is sufficient to enable any one to manufacture plaster casts out of the ash. Such a state of things is most undesirable, and should be at once abandoned.

The vendor of mustard is more to blame in most cases, for he is aware that it is an adulterated article. We have been informed, on good authority, that the brand "double superfine" is the one most exclusively sold in the better establishments, and that the British artizan, at the best, has to put up with a "fine quality." The present position of the mustard market is a specimen of the utter sterility of the laws regarding adulteration in this country.

DEATH BY ELECTRICITY.

M. Matteucci (*Chicago Med. Journal*) has recognised the fact that poisons do not all act in the same manner, and that, when the animal is killed by electric discharges, the excitability of the nerve by the current is destroyed. This observation ought to be taken into consideration in this regard, as it shows the danger of exciting the nerves too strongly.

* A specimen of the refinement of analyses, as these mustards generally contain about 0.04 per cent. of turmeric, yet can be readily detected.

WEDNESDAY, AUGUST 11, 1869.

THE MEETING AT LEEDS ON THE MEDICAL COUNCIL.

In the condensed report of the large gathering of the Profession at Leeds, published in our last number, may be read the exceedingly important fact that a large majority of those present, after a full debate, pronounced in favour of members of the Medical Council being elected by the members and licentiates of the bodies they represent. This is a great advance on the part of the Association, the executive of which has been so occupied with the desire to promote representation by means of members elected by registered practitioners as such, that it has quite overlooked the point so eloquently urged by the Rev. Dr. Haughton. We have so frequently insisted on the plan that Dr. Haughton triumphantly carried, that we cannot but rejoice to find an appeal to the sense of the Profession producing this striking result. We knew indeed that it must do so, because we are in a position to know how deeply the feeling has sunk into the Professional mind, that this scheme is at once simple and just, and, if carried out, would go far to redress many of the wrongs under which we labour.

It is now manifest that the scheme in question must form part of any amendment of the Medical Acts, and we completely agree with Professor Haughton, that it is wise to ask not this or that alone, but all that we desire; for it is as easy to pass a comprehensive measure of reform as a minor one. We have never advocated making this one reform of the Council a plea for legislative interference. We have rather held that the Legislature originally intended such a movement, and we are corroborated by the originator's letter to the Council. In that communication Dr. Prosser James showed that he submitted such a plan to the late Lord Palmerston's Government, and that the clauses of the Act embrace it, and were intended at the time to apply to that mode of electing the Council. From that time the question has never been at rest. The ruling bodies of our corporations usurped the authority to

nominate, but not without murmurs and protests. The University of London graduates spent some £100 in a lawsuit on the matter, and failed for want of energy and more funds. This was not all. Dr. Prosser James is said to have expended four or five times as much as this in preparing the way for an appeal to the law courts in reference to most of the corporations, and we are assured that the opinions he expressed in his letter to the Council are fortified by some of the highest legal authorities of the day. Last year the columns of the Journal of the Association witnessed how strongly his views were endorsed by many correspondents, and how widely they had spread through the Profession. The *Medical Times* has lately given expression to an approval only qualified by a desire to limit the numbers of the Council, and very naturally suggests an extension of the plan of grouping which exists in the case of the Scottish Universities. There is much doubt whether the Council should be curtailed in numbers, and our contemporary has done well to give it expression. The *Lancet* has admitted in several articles the fact that this plan is spreading, and in one or two distinctly approved it, although, with a jealousy unworthy of its history or position, it has attempted to attribute its origin to others—knowing full well that the origin had been clearly shown in these columns as well as in those of the *British Medical Journal*, both this year and last. The *Medical Mirror*, which all along upheld the direct election by registered men in its last number, pays a handsome tribute to the proposer of the other plan, and acknowledges how much it would effect. Lastly, the general press has thoroughly approved the plan of election in the manner we have advocated. With such a growing opinion there can be little doubt of the result, and the proposer of the scheme may be congratulated on its success.

We are not forgetting the astounding little counter-move at Leeds. After an Association has passed a vote it is the rule to abide by it. But those who had worked so ardently for the other plan apparently did not see that their hands were really being strengthened, and so asked leave not to consider the vote binding in communications with Government. This was a sad mistake. It produces on outsiders the impression that the few only cared for a hobby, and it will, unless care be taken, go far to weaken the effect of any communication to the Government that the committee of Council may adopt. On general grounds such reluctance of an executive to act with the great body evinces a want of harmony or a failure of insight which may be fatal to the influence of the Association. It is therefore strongly to be deprecated, and we were glad to hear some of the members speak out boldly on the point. It should have been remembered by all that an appeal had been made to a large meeting, and that the result was an immense majority for Dr. Haughton's resolution. Nothing could change that vote. No tampering could destroy the fact that, having discussed the plan, the meeting approved it. But, more than this, Dr. Haughton had put the case in its true light. The plans, as we have shown before, are not antagonistic, and the meeting would have made them supplement each other. Thus the Association would have invited the junction of the forces of those engaged in a common cause. Medical reformers have been too divided, and those who would partially reverse such a vote as this would withdraw the hand of fellowship from equally earnest labourers with themselves. The time is coming when all should be ready to unite in a great effort for the

common good. Much as has been the excitement caused by the question of the Medical Council, it will soon be eclipsed in far larger issues. We desire the Council reformed. We feel it might have reformed itself; but as it has refused everything, it is time for a great Medical reform to be undertaken by the Legislature. In view of the approach of this, we call upon all Medical reformers to take their stand together—to fight, not for the minor points, over which perhaps too much time and thought have been wasted—but to do battle for a measure broad enough to satisfy the Profession and protect the public.

SCOTLAND.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH, ON THE MEDICAL COUNCIL.

THE Royal College of Physicians deserves the gratitude of the whole Profession. It has spoken out on a topic which daily grows in importance, and, in doing so, has given utterance to the feelings of thousands of Medical reformers. It has in the strongest terms condemned the Medical Council. Here is the verdict of the College on the General Medical Council, about which we have had to speak so strongly:—

“That this College, after ten years’ trial of the Medical Act (21 & 22 Vict., cap. 90), is satisfied that it has not fulfilled either the wishes or the requirements of the Profession. That the College, while gladly admitting that the Medical Council have done a good deal to improve Medical education, is nevertheless of opinion that it has failed to deal with sufficient firmness with several Examining Boards who have refused to carry out the recommendations of the Council.

“That this College is of opinion that the Medical Council is not the best body to inaugurate any new measure of Medical reform.

“That the College, therefore, remit to the Council, with powers to prepare, for the approval of the College, a memorial to Her Majesty’s Government in regard to the necessity of a new Medical Bill, and to hold conferences with any other bodies in regard to it.

“That the Royal College of Physicians of Edinburgh is of opinion that the multiplicity of Examining Boards, each giving separate diplomas, is an evil.

“That the College is of opinion that it would be desirable if the various Examining Boards in Scotland would unite to form an entrance examination, leaving it to each of them to bestow, in addition, such diplomas as their charters entitle them to confer.

“That the College remit to the Council to endeavour to promote such a view by conference or otherwise.”

No one is likely to dispute that the Medical Council has proved itself incompetent to rule the Profession. It has turned a deaf ear to all who would have improved its constitution, and, wrapping itself in self-complacency, has forfeited the confidence of the Profession, the Government, and the public. Many have been those who thought its greatest fault was its care for the licensing bodies. The Edinburgh College, led by Dr. Alexander Wood, shows that some of these corporations are better than the Council. We sincerely trust that the other bodies will accept the invitation to a conference. By so doing they may retain all that is worth retaining of their privileges. If they do not they must take the consequences. The axe is laid to the root of every corporate tree, and some of them seem likely to be laid low.

There is only one point we should have wished further entered upon. The College admits its Fellows to vote in the election of its representative in the General Council. Is it prepared to extend the franchise to licentiates? This is a question that we think Dr. Alexander Wood should certainly have said something about. The battle on this point is, in fact, almost won. No Liberal Government will suffer the nomination of members of a reformed Council by narrow constituencies, and those corporations which demur to the full extension of the franchise are very likely to be left in the lurch altogether, and their diplomas looked upon merely as those of societies to which the entrance is chiefly restricted by the payments.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONIAL.

THE ceremonial of graduation of students in medicine took place on the 2nd inst., in the General Assembly Hall, which was filled by a gay assemblage of ladies and gentlemen. The graduates, dressed in their robes, occupied the central area of the hall. Vice-Chancellor and Principal Sir Alexander Grant presided.

There were twenty-six candidates who received the degree of Doctor of Medicine under the new statutes, and five under the old statutes. Thirty-nine candidates received the degree of Bachelor of Medicine and Master in Surgery, and five received the degree of Bachelor of Medicine only.

Sir Roderick I. Murchison received on this occasion the honorary degree of LL.D.

Notes on Current Topics.

Baby Farming.

AT the Guildhall, last week, a woman was brought up charged with starving and neglecting a child left with her by its mother to bring up. In defence, she said she had not been paid for several weeks. Though a year and three quarters old, the child only weighed 10 lb. 5 oz. The magistrate said it was a most cruel case.

Workshops’ Regulation Act.

MR. JAY, of the Regent-street Mourning Warehouse, has been fined for infringement of this Act. Personally, Mr. Jay has always been an advocate for the strict enforcement of such an Act, but it was shown that one of his superintendents had asked some of the young women to remain beyond the legal hour to finish some mourning required for a funeral. Of course, legally, Mr. Jay is responsible for the conduct of his superintendent, and was duly fined, although it was shown he had given strict orders not to infringe the Act. The fine will not be of any consequence to Mr. Jay, who will no doubt feel it quite right for the law to be thus impartially carried out. It would not have done to let off Mr. Jay, although personally he was not to blame.

Compensation for Railway Injuries.

A CASE against the London and North-Western Company was tried last week on the Northern Circuit. It

appears that the plaintiff had suffered in and been compensated for a previous accident, and was only beginning to do a little work when the second accident happened, and completely disabled him. Mr. Erichsen and Drs. Noble, Roberts, Webster, Mr. Beevor, &c., were engaged. The plaintiff was brought into court lying on his back, on a sort of stretcher. The Judge (Hannen) made some pointed comments on this kind of exhibition. It was of course done to excite the sympathy of the jury. It was stated that on the occasion of the former accident the patient was brought into court in the same way. The jury gave a verdict for £1,500, the same amount that the plaintiff had received as compensation for the first accident. Another case was tried against the Lancashire and Yorkshire Company, in which also Mr. Erichsen, Mr. Beevor, and others appeared. £2,000 damages were given. The railways will surely learn caution if costs can make them.

Toxicology Extraordinary!

OF all the strange results of the freedom of the Press, and the readiness of certain papers to indulge the *cacoethes scribendi* of their readers, the way in which nice questions of toxicology are discussed in letters to the daily papers is most remarkable. Dozens of letters appear, the initials subscribed to which mean absolutely nothing, and respecting the writers of which we can know as little, whenever a jury has returned a verdict of guilty against any one accused of murder by poison. The *Telegraph* particularly cultivates this kind of confidence in its readers, and its columns have lately teemed with letters, the purport of which was to show that Fanny Oliver was not proved guilty to the satisfaction of the writers. We do not object to this, nor do we care to inquire now as to the propriety of the commutation of sentence that has been granted. But we certainly would express surprise at the hardihood of some of the letter writers in attacking the scientific evidence at the trial, and setting up their own prejudices or misgivings against the skill of the chemical analyst engaged.

It would be comic, were it not such a burlesque on the solemn administration of the law, to note how the silly prating of anonymous correspondents seems to get the better of scientific facts. It is terribly amusing to read such criticisms and such simple explanations of the presence of "only a quarter of a grain of arsenic in the liver." If we were to believe all these people tell us, we might all be walking about with still larger accumulations of that mineral in our systems. What does it all amount to? That certain ignorant people have so high an opinion of their own knowledge and judgment, that they are ready to ignore the evidence of facts they cannot appreciate.

Well, perhaps that is no new thing in human history after all!

The Nature and Treatment of Cholera.

DR. MURRAY, Inspector-General of Hospitals in India, who has long been engaged, under official sanction, in instituting inquiries and in making research into the nature and treatment of cholera, is stated to have embodied and submitted to Government the result of his useful labours in a bulky and important Report. The Governor-General, after thanking Dr. Murray for his zealous devotion to the subject, has sanctioned the exten-

sive distribution of his Report throughout India, not, of course, as conveying the authoritative decision of the Government of India on so obscure and difficult a question as the nature and treatment of cholera, but for its own probable value, as embodying the deliberate views of an officer of long experience, who has devoted himself assiduously to the duties of his Profession, and especially to the consideration of this particular form of disease.

Health of Dublin.

IN the Dublin Registration District the births registered during the week ending July 31st, amounted to 155; the average number in the corresponding week of the years 1864 to 1868 inclusive, was 157. The deaths registered during the week were 122; the average number in the corresponding week of the previous five years was 134. Fever caused 10 deaths—viz., 6 typhus, 3 typhoid or enteric, and one common continued fever. Of the foregoing deaths from fever, one occurred so far back as June 15th, one on the 16th, another on the 18th, one on the 28th, and one on the 29th of the same month. Though these deaths took place in a public institution (Cork-street Fever Hospital), the registration of them was neglected until last week. Seven deaths resulted from scarlet fever; of these, one occurred on June 17th in Cork-street Fever Hospital. Measles proved fatal in 4 instances. Two deaths were referred to croup, one to whooping-cough, and one to diphtheria. The deaths from diarrhoea amounted to 4. Bronchitis was the cause of 8 deaths, and pneumonia of one. Five deaths were ascribed to inflammation of the brain, &c. Heart disease proved fatal in 8 instances, and aneurism in one. Inflammation of the stomach, inflammation of the intestines, inflammation of the covering of the intestines, and perforation of the intestines, caused one death respectively. Fourteen deaths were ascribed to pulmonary consumption, 11 to water on the brain, and 4 to mesenteric disease. Three deaths were attributed to cancer. The Registrar of No. 1 District, Kingstown, observes:—"The sanitary state of my district is most satisfactory. I have not one case of contagious disease on my dispensary register since last return." Two accidental deaths were registered—viz., a child, five years old, from drowning; and a man aged fifty-five, from concussion of the brain from a fall. Two suicidal deaths occurred: one by gunshot wound, and the other by wounds of throat.

Queen's University in Ireland.

AT a meeting of the Senate of the Queen's University, held on the 21st ult., the following Examiners were appointed for the ensuing year:—In Medicine, Professor Cuming, M.D.; in Surgery, Edward Dillon Mapother, M.D.; in *Materia Medica*, Maxwell Simpson, M.D., F.R.S.; in Medical Jurisprudence, Prof. Hodges, M.D.; in Midwifery, George H. Kidd, M.D.

Mortality among German Troops.

"It has been proved," says the *North German Correspondent* of Berlin, "by sanitary tables continued through a long series of years, that the annual mortality in the Prussian army, and at present among the North German troops, is on an average 69-70 per 10,000 men, while for the Russian soldiers it is 390, for the Austrian 280, for the French 190, for the Italians 150, and in the Belgian army

142. The last-named troops come, therefore, in a sanitary point of view next after the North Germans, although the mortality in a year amongst the former is more than double that of the latter. The comparatively large number of deaths in the Austrian service is attributed partly to defective hospital arrangements, and partly to the neglect of hygienic precautions and obstinate prejudice against ventilation on the part of the soldiers themselves. The rate of mortality in the English army (150 per 10,000) is more favourable than in that of France (190 per 10,000), in spite of the differences of climate and other injurious influences to which the British soldiers are exposed on colonial service."

Statistics of Suicide in Continental Armies.

ACCORDING to the statistics published by the *Gazette de Vos*, there were, in 1868, not less than 134 cases of suicide in the army of Northern Germany, to a total mortality of 1,344—a proportion of one self-murderer to each eleven deceased. This proportion is really frightful; it is four times that which exists amongst the civil population of the Empire. The statistics of suicide in other countries show that the proportion in the armies are—for Denmark, 1 in 3,900; Saxony, 1 in 5,000; Baden, 1 in 9,000; Norway, 1 in 9,000; Wurtemberg, 1 in 9,784; France, 1 in 10,000; Sweden, 1 in 15,000; Bavaria, 1 in 15,600; Belgium, 1 in 17,800.

THERE were 935 persons attacked with cholera in the district of Saugor from the 17th to the 19th June, out of whom 811 died. "How long," asks the *Jubbulpore Chronicle*, "will the district stand such frightful devastation?"

THE *Gazette Hebdomadaire* of Vienna announces that Professor Purkinje, of Prague, died on the 28th of July, in the eighty-second year of his age. He was one of the most celebrated physiologists in Germany, and his works on vibratile movements and the development of the egg are known to all the learned.

VON GRAAFE, the illustrious ophthalmic surgeon of Berlin, having lately returned from Italy, where he had proceeded for the good of his health, has, we regret to learn, lost all the benefit which he had derived from the change of climate, and will, probably, be obliged to abandon his labours and the practice of his profession to seek anew the beneficial effects of a warmer climate.

THE subscription opened by the friends of Trousseau has effected its object. Two busts of the lamented Professor have been executed: one, in marble, is to be placed in the assembly room of the Faculty of Medicine; the other, in bronze, is to be placed under the peristyle of the Hôtel Dieu. Not only have the expenses been amply provided for, but the balance of the receipts has enabled the committee to send to each subscriber a photographic proof of the bust, as a souvenir of the man in honour of whom the subscription was initiated.

THE report of the last sitting of the Academy of Medicine of Paris contains an interesting communication from M. Fauvel, on the mission confided to Dr. Proust for the purpose of informing the French Government as to the

measures taken by Persia and Russia to preserve Europe from a new invasion of cholera upon the points by which the terrible epidemics of 1832 and 1849 have penetrated to ravage the European Continent. The learned Inspector-General of the Sanitary Service has concentrated his attention upon the dangers with which the annual pilgrimage to Mecca threatens the world. M. Fauvel has not forgotten the melancholy results of past epidemics. It is necessary to ascertain whether Persia, on the one hand, or Russia, on the other, have kept the engagements on which they had entered to guard against new invasions of cholera. It is necessary for us to know in what condition of efficiency the sanitary arrangements of these States may be, and how much Europe has to fear from their carelessness. M. Fauvel demonstrated the urgency of this mission by the announcement that the cholera, which last year had manifested itself in Persia, and especially in Teheran, had just reappeared in this latter city.

IN one of the recent numbers of the *Wiener Wochenschrift*, Professor Braun, of Vienna, relates an extraordinary incident in his practice. Twenty-three hours after an operation for ovariectomy the patient died of hæmorrhage. At the opening of the body a morsel of sponge was found, which had been left in the abdominal cavity. All those present at the autopsy believed that the presence of the foreign body had in no respect contributed to the unfortunate termination. All the sponges had been counted, and it was found that the piece must have been broken off from one of them.

This incident has given rise to a civil action against the *Wiener Medicale Zeitung*. The circumstances had been reported in that journal, but by mistake were attributed to Dr. Billroth, who, being very angry, has commenced an action against Dr. Kraus, the Editor, for "publication of false intelligence;" and although he, repudiating any malicious intention, offered the fullest publicity to remedy the injury which might be caused, Dr. Billroth, nevertheless, persists in his action for damages.

THE CONTAGIOUS DISEASES ACT.

THE Select Committee appointed to inquire into the working of the Contagious Diseases Act, 1866, and to consider whether and how far, and under what conditions it may be expedient to extend its operation, have agreed to a report. The committee say in reference to the question whether it would or would not be advisable to extend the operation of the Contagious Diseases Act (1866) to the whole population, it is one which involves considerations of such magnitude, both social and economic, that they have thought they should best perform their duty by not entering on so large a field at so late a period of the present Session. Her Majesty's Government were not prepared, and had no intention to enter into the consideration of this question in the present year. Although the Act has only been in operation two years and a half, and at some stations only seven months, strong testimony is borne to the benefits, both in a moral and sanitary point of view, which have already resulted from it. Prostitution appears to have diminished, its worst features to have been softened, and its physical evils abated. In certain military districts the limit of five miles imposed by the present law appears to be insufficient. Testimony is borne to the fact that women reside just outside this limit to escape the operation of the Act, and strong representations have been made by some of the witnesses as to the necessity of extension. The committee are of opinion

that the limit may with safety and advantage be extended in military districts, where it is found necessary to do so, to a distance of not more than fifteen miles, which is the limit of the powers of the metropolitan police in other respects. The 17th section provides for the voluntary submission by women to medical examination, but does not give sufficient power to secure their continued obedience to the requirements contemplated by the 19th section. To remedy this the committee recommend that the notices of visiting surgeons shall have the effect of a warrant, which shall be an authority to the police to apprehend a woman refusing to appear on the day appointed. Power should also be given to the visiting surgeon to order the detention of women. The evidence seems to point to the necessity of extending the limitation of detention, under section 24, from six to nine months. It has been shown that the certificates given under the Act on discharge from hospital are sometimes improperly used, and often change hands. The committee recommend that the certificate on discharge shall in future remain in the hands of the inspector of police.

An important modification of the Act is suggested by what appears in evidence,—viz., that in the first four months of this year, out of 700 women of ill-fame in Devonport, 41 were undoubtedly restored to a virtuous life by the direct and indirect influence of the Act, and 29 more left the district. It appears that many of these women would object to apply to a justice in open court for a discharge from attendance, but would feel no such objection to be discharged by the medical officer under whose care they had been. The committee therefore propose to modify clause 33, by omitting the last half after the words "certified hospital," in order to insert a provision that a woman applying for relief from detention and examination might make application on that behalf to the visiting surgeon, who, on ascertaining through the inspector of police that she had abandoned a life of prostitution, might, if he saw good reason, order her release from further attendance; such order to be equivalent to one issued by a justice. The committee observe that, whilst it would be inadvisable to subject non-commissioned officers and married men of good character to examination, it appears not unreasonable that, for the general good of the service, other soldiers should be periodically examined; and the committee have reason to suppose that such a system, properly conducted, would not prejudice the service. The expense entailed on the country by extensive disease among the troops, the injury inflicted morally and physically upon the men, seem to point to the urgent necessity which exists for adopting every possible means to arrest the spread of this contagion, no less than its duration. The committee have not taken professional evidence as to the practicability of extending such a system of periodical examination in the navy, but they recommend that it should be considered by the Admiralty. The committee have received evidence as to the prevalence of disease at Aldershot, spread not only by the common prostitutes who resort to the camp, but by women brought to it from considerable distances by tramps, who live on the earnings of these women. It is possible that this evil exists at other camps. It would be, in the opinion of the committee, desirable to meet this by special penal legislation.

The committee recommend that in addition to the power of extending the operation of the Act at military stations to a distance of fifteen miles instead of five miles, the following places should be added to those now scheduled in the Act:—Gravesend, Maidstone, Winchester, Dover, Walmer and Deal, Canterbury, Colchester, Devonport, Portsmouth, Woolwich, and Windsor.

The committee remark, in conclusion, that whilst they have confined their investigations to the object of securing greater efficiency in the treatment of these diseases at military and naval stations, they recommend that further inquiry, by a committee appointed early in the next Session, should be instituted with a view of ascertaining

whether it would be practicable to extend to the civil population the benefits of an Act which has already done so much to diminish prostitution, decrease disease, and reclaim the abandoned. The committee have examined Mr. Simon, the medical officer of the Privy Council, as to the nature of the evidence which should be prepared before this question is referred to a parliamentary committee, and they recommend that his suggestions on this head should be adopted by Her Majesty's Government.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ACTION OF HYDROCHLORIC ACID ON MORPHIA.

MR. MATHESSEN and Mr. Wright find that when morphia is subjected to a temperature of 140°, in a sealed tube with a great excess of hydrochloric acid, an alkaloid is found, differing very considerably in its properties from morphia.

It would appear that the new base is simply formed from morphia by the abstraction of the elements of water.

The discoverers propose to give the name of apomorphia to this alkaloid.

The physiological effects of apomorphia are very different from those of morphia. A very small dose produces speedy vomiting and considerable depression; but this soon passes off, leaving no after ill effects.

Dr. Gee finds that one-tenth of a grain of the hydrochlorate subcutaneously injected, or one-fourth of a grain taken by the mouth, produces vomiting in from four to ten minutes. A gentleman allowed himself to be injected with one-tenth of a grain, which produced vomiting in less than ten minutes. Dr. Gee concludes that the hydrochlorate is a non-irritant emetic, and a powerful anti-stimulant.

In a second paper they also find that, on submitting codeia to the action of hydrochloric acid, a similar reaction is produced, and a crystalline chloride of apomorphia was procured. Apomorphia procured from this source gave the same qualitative reactions, and produced the same remarkable physiological effects.

PROTOXIDE OF NITROGEN.

M. STANISLAS LIMOUSIN has written a long memoir on the above subject (vide *Journal de Pharmacie et de Chimie*, June), which possesses some interest from a therapeutical point of view. The author was struck by observing the great solubility of the gas in water. Having partially filled a jar with cold water and this gas, he was surprised, on agitating it quickly, to find the cork of the jar sucked in, with a loud noise. On being measured, it was found that the solubility of gas in water was not half, as given in most of the works on chemistry, but was volume for volume—that is to say, the solubility at ordinary temperature was volume for volume, and equal to that of carbonic acid. We are, therefore, able to obtain a solution under the ordinary atmospheric pressure, one volume of gas to one volume of water, or one-third of oxygen. The solution has a sweet taste, which is slightly insipid, but renders the water more agreeable to drink than when it is pure. It communicates a peculiar taste to wines and such like liquors. When the solution is made under pressure, and some volumes of the gas are dissolved, this sweet taste is much more strongly manifested.

The author, although he does not pretend to prove that there is any complete analogy between this definite chemical compound and atmospheric air, still he insists upon the little stability of protoxide of nitrogen under the influence of certain chemical agents and certain physiological conditions. It decomposes, under very feeble influences, into nitrogen and oxygen. It is, therefore, in M. Limousin's opinion, capable of playing other parts besides that of an anæsthetic agent.

ON THE REACTIONS OF CHLOROFORM.

M. BAUDRIMONT points out certain peculiarities as regards the reactions of this body. Chloroform is decomposed, under the influence of caustic potash, into an alkaline formate. When some drops of that fluid are heated with a few drops of

Frommherz's liquor (potassio-tartrate of copper), a hydrate of a yellow colour is deposited, which, on boiling, soon changes to the red oxide. This reaction is so delicate that it only suffices to agitate one or two drops of chloroform with 100 centimètres of water; this solution will instantly reduce the copper solution. The remarkable point, however, is, that soluble formates do not produce this reaction. It is evident, therefore, that the formate only produces this reaction at the instant of its nascent condition.

Literature.

THE VEGETABLE NEUROTICS.*

OUR readers are well aware that the author of this volume has for a long time occupied himself with original researches into the action of drugs, and that many of his conclusions have been generally accepted. They will therefore expect in this book a considerable amount of original investigation and an authoritative account of the author's views. They will not be disappointed. Dr. John Harley believes that we may find in some one of the lower animals an exact reproduction of all the variations that we observe in the action of any one drug on the human economy. He consequently anticipates that sufficiently numerous experiments on various series of animals will bring to our knowledge all the phenomena that the drug experimented with can produce in man. It is not necessary to accept this as the whole truth to see the value of such an idea as a guide to investigations of this nature. We find certainly in the animal kingdom various degrees of development of the nervous system, and we find drugs selecting various nervous centres on which to exert their powers. It does therefore seem natural to select certain animals for experiment that seem thus, so to say, adapted for our purpose; and, therefore, without committing ourselves to this guide as unreservedly as Dr. John Harley, we are very happy to follow him in his experiments, and learn from them all we can. There is abundant room for inquiry in this department of knowledge, and we welcome the book before us with the feeling that it is likely to do much good. Between scepticism on the one hand and blind credulity in the oft-repeated statements of too many text-books, there is some fear lest the truth should remain hidden when it might be brought to light. Such investigations as Dr. John Harley's are therefore of double value. They are not only to be welcomed for such truth as they establish, but as pointing out the direction in which the search for therapeutical knowledge should be continued.

STRICTURE OF THE URETHRA.†

THIS pamphlet seems to us the work of one who is a good observer of the attendant phenomena of a diseased condition, as well as an ingenious practical surgeon. The main point of the work is to make known the author's invention for the cure of stricture of the urethra by boring through the obstruction by means of a screw dilator. The mechanical appliances for accomplishing this are very simple, and are fully described at page 17, with all the precautions necessary to ensure a good result. That highly satisfactory results, with small suffering to the patient, follow upon Mr. Aspray's plan of treatment is shown in the cases published, from an experience extended now over some years; and we should advise all practical surgeons to study this small treatise on stricture and its treatment.

BATHS AND WELLS.‡

DR. JOHN MACPHERSON publishes a very elegant little

* The Old Vegetable Neurotics, Hemlock, Opium, Belladonna, and Henbane; their Physiological Action and Therapeutical Use Alone and in Combination. By John Harley, M.D. London: Macmillan.

† Stricture of the Urethra: its Safe and Rapid Cure by the New Screw Dilator, with Remarks on its Prevention and Diagnosis. By Charles Owen Aspray, M.D. F.R.C.S.E.; for four years Resident Medical Officer at St. Peter's Hospital for St. one; Consulting Surgeon to the Islington Provident Dispensary; Fellow of the Medical Society of London.

‡ The Baths and Wells of Europe; their Action and Uses. By John Macpherson, M.D. London: Macmillan.

volume, which, if rather sketchy and partaking somewhat of the guide-book character, will be an agreeable companion to those who may be on their way to the more frequented continental bathing-places. We feel with our author that our English pilgrims to the wells seem almost all to flock to Germany, while France and Italy might often be visited just as well or better. We are therefore glad that Dr. Macpherson gives a fair notice to a number of French, Italian, and Spanish bathing-places. We take this opportunity also of remarking that too often people take a foreign tour from mere fashion or caprice, when the resorts of their native isle would be more beneficial. Things at home are apt to be neglected for those at a distance.

While on this subject we may notice that we have received another edition of Dr. Edwin Lee's work* on the Baths of Nassau and Homburg.

A book written by an author who has for years been recognised as an authority on baths, and which has now reached a fifth edition, requires no introduction; it suffices to chronicle the fact of another edition being called for. Dr. Lee is always visiting the various bathing places, and consequently the successive editions of his descriptions of them are regularly brought down to the latest dates.

Transactions of Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE Medico-Psychological Association held its twenty-fourth annual meeting, at York, on the 2nd inst. President, Professor Laycock, of Edinburgh, who gave a dinner at Harper's Hotel on the occasion.

Dr. Laycock, on taking the chair, gave an address, in which he noticed more particularly the character, objects, and constitution of the Association. As to the scheme for amalgamating the Association with the Royal Society of Medicine, he was adverse. A Psychological Section would, he thought, be a valuable addition to the proposed society; but he felt that if the Association merged into such a section it could not carry out all its present work, and that consequently a modified and much less useful Society would still remain.

About twenty-three new members were elected, and subsequently in the proceedings five gentlemen were elected honorary members.

Dr. Boyd was elected president for next year, Dr. Tuke was re-elected honorary secretary, Dr. Paul honorary treasurer, and Drs. Robertson and Maudsley editors of the Journal. Some additional names were also added to the Council. In returning thanks for his re-election, Dr. Paul, the treasurer, read the balance-sheet, showing a sum of over £40 in hand.

A discussion took place on the question of amalgamation of the Association with the proposed Royal Society of Medicine, and ultimately a resolution was carried for a committee to consider the question, and to report to a future general meeting.

A committee was also formed, consisting of the President, the past Presidents, and Drs. Arlidge, Christie, and Crichton Browne, to reconsider the laws of the Association.

The scientific proceedings were opened at the second meeting with a speech by Professor Laycock. A vote of thanks was voted to Dr. Laycock, and carried by acclamation. The address will, we understand, be printed in full in the Journal of the Society.

Dr. Richardson read a paper "On Physical Disease from Mental Strain," urging that in this day, when the mental powers were so terribly overtaxed, this study demanded earnest and immediate recognition by the general not less than by the psychological physician.

A discussion, in which many members took part, followed the reading of this paper. The common view that insanity is not induced by mental work was very strongly confirmed.

Mr. Lockhart Clarke, F.R.S., read a paper "On a Case of General Paresis," and showed some remarkable specimens of diseased brain taken from a patient who had died under the care of Dr. Gairdner, of Glasgow. The brain exhibited a considerable number of small oval cavities, sharply defined, and of sufficient size, we should think, to hold an oat-grain. The

* The Baths of Nassau, Homburg, and Nauheim. Fifth edition. By Edwin Lee, M.D. London: John Churchill and Sons.

case was thought by some of the members to be unique, and certainly the disease it represents has not before been described so as to be easily recognised. It is now, however, thanks to Mr. Clarke's skill in preparation of brain-matter and admirable method of observation, so well defined, that we may all be ready to follow up research on the subject.

Mr. Clarke had a second paper, which he could not read, the time being too short; but at the request of the President he gave a brief and lucid demonstration of the anatomy of the brain, dealing especially with the plan of the convolutions.

Dr. Tuke read a paper entitled "An Apology for Lord Brougham on Psychological Grounds;" and Dr. James Sabben read a very interesting paper on "The Consideration of Ritualism with reference to its Influence on Insanity."

The members of the Association dined together on Monday, the 1st inst., under the presidency of Dr. Laycock, and in the company of the Lord Mayor of York (Mr. Carron Hey), and other well-known local visitors. After the dinner, Dr. Christie gave a *conversazione* at the Assembly Rooms: Dr. Proctor, of York, gave demonstrations of various electrical phenomena; Dr. Clifford Allbutt, of Leeds, exhibited experiments with the ophthalmoscope; and Mr. Lockhart Clarke described and showed microscopical preparations of the nervous system.

The next annual meeting of the Medico-Psychological Association will be held in London.

Correspondence.

TO OBTAIN "CONTINUED EXTENSION" IN THE TREATMENT OF FRACTURES, WITHOUT USING THE PULLEY AND WEIGHT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If space will admit, will you kindly allow me, through the columns of your influential journal, "THE MEDICAL PRESS AND CIRCULAR," to express my entire agreement with Dr. Johnson, of Kilkenny, when he writes, alluding to the treatment of fractures by "continued extension," "It matters little to science or mankind who was the originator of this plan." "Is the plan useful and effectual?" The latter is the question which ought to occupy the foremost place in the minds of those anxious to forward the interests of their profession, and to enlarge the means at our disposal for the relief of the suffering. So much has been written upon the treatment of fractures by the pulley and weight, that I shall not allude to it again; but I wish to draw attention to another method of making "continued extension" in treating fractures, which I first saw put into practice through the kindness of Mr. Braddel, house surgeon in the Leeds General Infirmary, and by which I have since obtained the happiest results in the case of a woman, over sixty years of age, who fractured the right thigh at the junction of the upper and middle third of the femur. I am aware that this plan of treatment is known to many, but as I have not seen a description of it in any of the different surgical works, or the various handbooks upon bandaging and surgical appliances; and as it seems to be attended with many advantages and to be easy of application. I think it would be well to make it more generally known through your columns. To carry it into effect there are required—1st. A slight modification of Jiston's long splint, having the two ordinary holes at the upper extremity, a large opening for the external malleolus and the lower extremity, not split as in the ordinary splint, but having a small light iron bar, about six or seven inches in length, attached to it, perpendicular to the surface to be applied to the limb, the bar being notched on the side farthest from the sole of the foot.

2nd. A pad, narrow and somewhat longer than the splint, to be applied to its whole length, and to allow of its doubling over the upper extremity to protect the armpit; this pad to be secured in position by several pieces of tape.

3rd. A couple of small pads to be placed above and below the external malleolus, in order that the splint may make no pressure, even if the hole and malleolus do not correspond.

The injured limb is prepared as for the plan of extension, by pulley and weight, by placing broad bands of adhesive plaster along each side of the calf of the leg, a loop being left below the sole of the foot; a roller bandage is then applied from the foot to the knee. The splint and padding are next adjusted,

the small additional pads being placed above and below the external malleolus if necessary; the peroneal band ordinarily used is then placed in position, the foot is secured by a strong piece of tape passed through the loop already mentioned, and tied to the cross-bar projecting from the lower extremity of the splint. Counter extension is then made by tightening the tapes attached to the peroneal band, securing them through the holes in the upper end of the splint. A roller bandage from the foot to the knee, and a broad flannel bandage round the body and upper part of splint completes all that is necessary.

This method possesses two great advantages.

1st. It is easy of application.

2nd. The traction being made in the long axis of the limb, and being easily regulated as to amount, the risk of deformity and shortening is lessened.

When necessary, antro-posterior and lateral scored splints can be used with this method to assist in the coaptation of the fractured portions of bone.

Hoping this communication may be deemed worthy of a place amongst the many valuable contributions to the literature of our profession contained in your widely circulated journal,

I am, Sir, yours, &c.,

JOHN W. MARTIN, M.D., M.Ch. Q.U.I.

THE CATHOLIC UNIVERSITY OF IRELAND.

FACULTY OF MEDICINE.

Honour Examination for the Summer Class Prize.

July 1, 1869.—Morning.

MATERIA MEDICA AND THERAPEUTICS.

Examiner, Professor QUINLAN, M.D., T.C.D.

(Chemical Formulæ may be written either in the new or old notation.)

1. Give the experimental and other proofs by which it can be shown that the majority of medicines produce their effect through the blood.
2. Describe the method of preparation and the therapeutical action of sulphate of quinia.
3. What are the principal disinfecting and deodorizing agents?
4. Describe the medicinal uses of iodine and iodide of potassium.
5. Explain the chemical composition and medicinal uses of hydrocyanic acid. Mention some of the tests by which it may be recognized.

Honour Examination for the Summer Gold Medal.

July 3, 1869.—Morning.

1. Describe the principal anthelmintic agents.
2. Explain the method of preparation and the medicinal uses of hydrochlorate of morphia.
3. What are the principal preparations of mercury?
4. Describe the therapeutical applications of antimonium tartaratum. Contrast its action in cases of sthenic inflammation with that of mercury and venesection.
5. State the medicinal uses of arsenic. Mention the train of symptoms which indicates that this drug is beginning to act as a slow poison.

TREATMENT OF RETROVERSION OF THE UTERUS.

J. Byrne, M.D., Surgeon to St. Mary's Female Hospital of Brooklyn (*Am. Jour. of Obstetrics*), in a paper on "Retroversion of the Uterus," stated that there is no malady to which females are more subject than chronic metritis, and this condition should always receive the first and most careful attention of the physician. He also remarks, that as dilatation of the os internum is a primary and essential step in commencing the topical part of our treatment, and as it is often impossible to insert a sponge-tent beyond the cervix, he has found those formed out of sea-tangle invaluable, as, when inserted once or twice, there is no difficulty in using the larger kind made of sponge, if deemed necessary. Nevertheless, it is worse than folly to hope for any permanent benefit from topical measures merely; and, on the whole, constitutional treatment, and a strict observance of hygienic rules, are not only absolutely indispensable, but without them every other means will avail nothing.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

ON July 10, Dr. Evory Kennedy replied as follows:—

Sir, in answering the criticisms on my paper, I must, in the first place, say I was not ignorant of the effect likely to be produced by grappling with an evil such as I felt it my imperative duty to expose, and, by the weight of public opinion, if possible, to remedy.

Neither was I ignorant of the fate that usually attends reformers.

I was warned on all sides not to bring a hornet's nest upon me, and cautioned not to disturb the equanimity of the physicians of Dublin by proposing impracticable changes in their darling institutions, hitherto the pride and boast of our city.

Sir, my motives forbade my giving ear to those timid counsels. My reliance upon the strength of my cause, which is yours alike, coupled with the estimate in which I hold the sound-thinking, liberal-minded, and philanthropic members of my Profession, led me to the conviction that the Profession, in this city, would never lend themselves to a feeble attempt to stifle or crush truth, if fairly and manfully brought before them.

It would have been easier for me to send my paper to the press, and avoid the ordeal of a *vive voel* discussion, with all its excitements, irritations, and personalities. But this plan would have failed in accomplishing the objects I had at heart, namely, eliciting fully all that could be said against, as well as for, the proposed changes; to meet objections fairly; and, further, to draw the attention of the whole Profession to the importance of the subject, and what I considered the crying nature of the evil, as the best and speediest means of effecting its remedy.

From this it will be understood that I was quite prepared to expect an animated discussion, with much discrepancy of opinion. The mildest of our poets extolled the use of the *animated no!* and a discussion cannot proceed without it.

I am bound to say that this debate has proved no exception to the rule; for, although some important points have been quite overlooked, and although some statements have been repeated and reiterated, which, in my judgment, do not touch my arguments at all, or else misrepresent them, still I will candidly admit that my opinions and facts have been on the whole fairly and fully as well as freely discussed.

I purposely and carefully abstained from using personal allusions, or warring with individuals. My hostility was directed against a system for which no person, living or dead, could individually be held responsible. The system of large lying-in hospitals was in operation before the birth of the fathers of the present generation, and it was due, in a large measure, to the benevolent exertions of the physicians of an earlier period.

The somewhat novel position in which I find myself placed of having to answer, at one and the same time, the objections and criticisms of sixteen learned doctors poured upon me, "quick, thick, and heavy, like a thunder shower," imposes on me a difficulty not easy to surmount, with due consideration of your time and of the task before me. Fortunately that task has been lightened by the fact that most of my commentators have answered themselves and each other. I was in hopes that what remained to be done by me might have been done by grouping my critics; but this I found impossible to do

satisfactorily. I am forced, therefore, to take them separately. I shall do so in the order in which each of the seventeen gentlemen spoke.

Dr. Johnston, the present master of the Dublin Lying-in Hospital, began the debate, and I shall deal with the salient points of his paper. He says he would be *wrong* in *not* contradicting my assertion, that the intention of Moss in relieving the miseries of lying-in women has failed, because the exertions of its masters have not rendered it as healthy as one could almost desire.

But it is proved that the mortality of the hospital has been for the last fifteen years 1 in 31. Unless, then, he looks upon the death of so large a proportion of patients as Moss's intended means of relieving them from their miseries, it follows Dr. Johnston *was wrong* in contradicting me, and that he is equally *wrong* in his other conclusion, that the hospital has been rendered *as healthy as one could almost desire*.

Dr. Johnston says that he has succeeded in maintaining a perfectly pure and innocuous atmosphere in the lying-in hospital, and continues:—"I may *certainly* say that anything like a *miasm* or *poison* does *not exist*, and confidently affirm that nothing approaching to contagion has appeared." Yet afterwards Dr. Johnston answers his own assertions by saying: "No doubt we have had deaths from metria, but in almost all instances they were either victims of seduction, &c., or others labouring under distress of mind."

Dr. Johnson says my statements are based upon wrong hypotheses.

Negatur; the hypotheses are strictly correct; that is, if Dr. Johnston's objections deal with what may be regarded as bearing upon the hypotheses he alludes to. Let us take them in detail.

Dr. Johnston cannot see why puerperal fever should prevail in the lying-in hospital when fever, typhus and erysipelas, prevailed in medical and surgical hospitals.

Very possibly. Neither do I *quite*, although I fancy we shall all soon see. But I know by experience *it is a fact*. So did the late Dr. Collins and the late Abraham Collis; so did the late distinguished Dr. Joseph Clarke and Dr. Labatt.

Dr. Johnston can't conceive why, because it frequently happens that puerperal fevers follow the introduction of these zymotic diseases into the lying-in hospital, that hospital should be charged with being the habitat of such a poison, or that zymotic disease in any way engendered it.

I can't conceive how we can arrive at any other conclusion from the frequency of the one following the other than that they stand in the relation of cause and effect. Although the hospital is charged with being the habitat of puerperal fever—a fact which cannot be disproved—it is not so charged because it may be specially engendered by the introduction of a case of zymotic disease (see Propositions 4 and 5).

Dr. Johnston can't admit that puerperal fever prevails epidemically in hospitals.

It must do so if the great hospital be its habitat; and this, although a self-evident fact, has been proved by me over and over again.

Dr. Johnston affirms it is not correct, in fact, unjust, to say that when puerperal fever appears it *generally* first shows itself in the great hospitals.

Not only is this the fact *generally*, but it is notorious that it often shows itself and commits dire havoc in our hospitals without extending, epidemically or at all out of them (see Dr. Joseph Clarke's letter to Sir C. M. Clarke, *infra*).

Dr. Johnston adds, after dwelling upon the precautions and advantages of the hospitals as compared to the hovels of the poor:—"It is hardly, if at all, possible that malaria, or miasm, or any poison, could find a habitat in the hospitals."

But it does, and does to such an extent that the mortality in all the great lying-in hospitals in Europe, notwithstanding

all the precautions adopted, has forced itself upon public and professional consideration, and we are here to investigate the causes of this *impossibility* according to Dr. Johnston.

Again, Dr. Johnston and his assistant deny the existence of a noxious atmosphere in the hospital during their period of connection with it, or from May, 1868, to May, 1869. The latter gentleman asserts that the present death-rate is much lower than Dr. Kennedy's calculation, based on the average of the last fifteen years, leads him to think it is. Fortunately, or, rather, I should say, unfortunately, he answers this question so completely in disproving his own assertions that nothing more remains but to adduce his own statistics. Need I say that it is to me a matter of pain and regret, as a governor of the institution, my being obliged to prove that this gentleman's statistics do not confirm the statement of so marked an improvement as they led us to expect? His statistics for the year 1868 are that there were 1,132 deliveries and 29 deaths, but of these there were, as far as I can elicit, 4 deaths in the chronic ward, which are not to be taken into account. If I am in error in this deduction, it is not my fault, as the report did not, as it ought to have done, give us the exact number from all causes, metria, of course, included. But 25 deaths in 1,132 leave a little over 1 death in 45. Now, in the fifteen years, from 1854 to 1868 inclusive, the fifteen years for which I take my average as establishing endemic disease, there are six years in which the death-rate is more favourable to the hospital than that of last year, of which Dr. Johnston and his assistant speak so confidently of "*nothing* like miasm existing," in the very same breath that they admit 18 deaths by zymotic puerperal fever on the high average of 1 death in 63 from this disease alone. To prevent mistakes on this subject we shall give the death-rates for the seven years alluded to, bearing in mind that the gross death-rate of the last year by their table, errors excepted, is 1 in 45½. In 1854 the death-rate was 1 in 53; in 1856, 1 in 64; in 1857, 1 in 46; in 1859, 1 in 66; in 1860, 1 in 54; in 1864, 1 in 46; and in 1865, 1 in 44.

Although I have deemed it necessary, in order to draw a fair comparison with other tables of mortality, to deal with the gross mortality in discussing this question, I am perfectly satisfied to take the statement of the 18 cases of metria out of 1,132 deliveries as conclusive evidence that the disease still holds its habitat and haunts the wards of the Dublin Lying-in Hospital, the large mortality of 1 in 63 *by metria alone* amply confirming this statement and that upon the statistics furnished by the present resident assistant.

But, sir, I will candidly admit, had it been otherwise, and had the tables furnished from May, 1868, to May, 1869, afforded a different result, had the death-rate fallen to 1 in 66—nay, to 1 in 100—or risen to its highest year (1862), 1 in 14, it would not in the slightest degree have affected the case I have made, or the necessity that exists for dealing with this important question. It did not require an occasional improvement in the mortality, extending, perchance, over a year or two, aye, or three years, to convince those who have studied this disease philosophically and free from prejudice, that it is fitful and capricious in its appearance, disappearance, and duration. My two nights' efforts to elucidate the laws which regulate this disease must have proved nugatory if this, one of its universally recognised laws, has not been impressed upon you.

I have here selected the points of Dr. Johnston's speech which appear to require an answer. The rest of his observations may be described as a eulogistic description of the management and advantages of the lying-in hospital, in which I should fully agree if its defects in construction were remedied. But with his conclusions, and with his arguments, meant to explain why it should be "as healthy as one could desire," and with his commendations of its construction, which I have pronounced and maintain to be "faulty"—with these I disagree,

simply because the experience of the hospital has proved that it is *unhealthy*, and that upon Dr. Johnston's own showing. For, surely, where all the other advantages are so great, and arrangements so perfect, the tenor of his own reasoning leaves me no alternative but to ascribe its unhealthiness to its *construction*, which I affirm, and Dr. Johnston thus proves, to be "*faulty*."

Now, wherein lies this faultiness of construction? In its being a double house, with an intermediate corridor, converting four great wards, with nine beds in each, and eight smaller wards, with three beds in each, into one great warren or plateau of connected rooms, with a similar plateau over it, with perforated openings in the ceiling of the lower corridor, which secures the same atmosphere pervading both corridors and the chambers. A generally commingling atmosphere is thus secured through doors, staircases, and perforated openings, so connected throughout that miasm must pervade all, if once generated. In fact, so constructed that isolation is totally impossible, as it is impossible to open a door, or to go in or out of any room in the building, without diffusing the tainted atmosphere, if it exist, throughout the whole structure.

I submit, then, that my original statements are confirmed, and Dr. Johnston's objections answered in the most conclusive manner, by the statistics furnished of the present state of the hospital by his own assistant.

Dr. Kidd, whose views appear to me more advanced upon the subject under discussion, and to approach more nearly to the state in which experience has now landed us, than any other of my commentators, leaves very little at issue between us. In fact, after examining my tabulated analysis of the speaker's, criticizing my thirteen propositions, I find that, directly or indirectly, he agrees with most of the propositions, and as he is about to give the best practical test of this in the manner in which the new wings of the Coombe Lying-in-Hospital are to be constructed, I sincerely deplore that he should be only *almost*, and not *altogether*, convinced of the necessity of complete isolation; for an error in this respect now will perpetuate this deplorable and yet preventable mortality, as if the modified attempt at isolation, as recommended in the resolutions at the Paris conference in 1866, which he describes as about to be adopted in the Coombe Hospital, be carried out, it may help to delay the progress of this great question for an infinite period. That it may lessen the mortality is quite impossible, but that it will prevent metria I do not anticipate; and whichever it does, if it leave the depression on the public mind either that enough has been done in this experiment, or that nothing more need be attempted, as this has failed, then, I am justified in saying that the change contemplated, by its failure or partial success only perpetuates the mortality.

(To be continued.)

Medical Gleanings.

CASES OF OVIARTOMY.

Dr. Henry Miller, late Professor of Obstetric Medicine in the University of Louisville, Ky. (*Am. Jour. Med. Sciences*), has always regarded the operation of ovariectomy with some degree of aversion. The uncertainty that must hang over the diagnosis in some cases, notwithstanding the improved methods of investigation, makes him hesitate and ponder long before he can bring himself to the point of laying open the cavity of the abdomen, and sweeping it with his hand to determine the nature of the tumour and the possibility of its safe removal. He holds that it is an impossibility to know of a certainty, before the operation is commenced, whether or not there are adhesions of the tumour of such a nature as to render it hazardous, if not impracticable, to extirpate it. He prefers the ligature to Mr. Wells's clamp, in cases of short pedicles, and asks, what evidence have we that the clamp, or any other

of the numerous methods of treating the pedicle which have been devised, is preferable to the ligature as used by Dr. Ephraim McDowell, of Danville, Kentucky, who first conceived and executed the operation of ovariectomy? If we look into Mr. Wells's book, we shall find that out of 114 cases of completed ovariectomy, in nearly all of which the clamp was used, 75 recovered, 39 died; 65 per cent. recoveries. Dr. Clay's cases, up to the latest date he had access to; numbered 110, of which 76 recovered, 34 died; 69 per cent. recoveries, 4 per cent. in favour of the cases in which the ligature was employed.

A. FREQUENT CAUSE OF FACIAL NEURALGIA.

Dr. Fort, of Paris, believes that facial neuralgia is often produced by a lesion of the buccal mucous membrane immediately behind the molars, and produced by the evolution of the wisdom tooth.

REFLEX IRRITATION FROM THE RECTUM A CAUSE OF UTERINE DISEASE.

J. C. Nott, M.D., N. Y. (*Am. Journal of Obstetrics*), reports an interesting case of dysmenorrhœa depending upon the engorgement and spasmodic contraction of the internal os, caused by reflex irritation from the rectum. The rectum presented on examination three external and two internal hæmorrhoids, which were removed with scissors and ligatures. To palliate the uterine pains, he inserted into the vagina a soft, round sponge, about the size of a pullet's egg, saturated with a solution of morphine and sulphite of soda, in the following proportions: R Sulph. morphine, gr. v.; Sulphite soda, ʒ ss.; Aqua, O j. In this case the sponge, prepared in this way, and tepid vaginal washes of salt-and-water, were continued for a month, during which time she was comfortable. In conclusion, he never treats uterine affections without inquiring minutely into the condition of the rectum. Hæmorrhoids, small ulcers, irritability, spasmodic contraction of sphincter coccydynia, are common causes of affections of the uterus, as well as vaginismus and other affections of the vagina. With regard to the use of sulphite of soda, the objects in using it were two: *First*, it has gained some reputation as an application to inflamed surfaces; *second*, it is an antiseptic which would prevent the sponge from becoming foul.

ACNE ROSACEA WITH HYPERTROPHY OF THE NOSE.

Guibout (*Annales de Dermatologie et de Syphilographie*, No. 2, 1869) discusses the subject of acne rosacea with hypertrophy of the nose, and relates the case of a man, 45 years of age, who had used every form of external and internal treatment with no success. From six to ten incisions were made into the nose every two, three, or four days; the bleedings were encouraged for from five to ten minutes; then lint soaked either in Goulard's lotion, or in a concentrated ammoniacal solution, was applied with some pressure; the application was kept moist. With this treatment the hypertrophy of the nose rapidly subsided, due to adhesion of the walls and obliteration of the distended blood-vessels. This treatment was suggested by Hebra, five years ago.

ENLARGEMENT OF THE PAPILLÆ IN LICHEN RUBER OF HEBRA.

Dr. Neumann, in the *Proceedings of the Vienna Academy*, certifies that the enlargement of the papillæ in the lichen ruber of Hebra is due to increase in the size of the capillary loops, and to cells deposited along the walls of the blood-vessels. The outer root or sheath of the hairs at the base of the hair-follicle presents teat-like prolongations that indent the hair-follicle, so that it looks like a venous gland, and the hair splits up from the bulb.

CARBONIC ACID EXHALED.

Dr. Edward Smith (*Chem. Gazette*) ascertained that the amount of carbonic acid exhaled by the lungs was in proportion to the actual work performed.

During sleep it was at the rate of.....	293	grs.	per	hour.
When lying down and approaching sleep	355	"	"	"
In a sitting posture.....	491	"	"	"
When walking two miles an hour	1,088	"	"	"
" " three " " "	1,552	"	"	"
And when working at the treadmill	2,926	"	"	"

MAMMARY GLAND REMOVED BY CAUSTIC ARROWS.

Dr. Gill (*Med. Archives*) lately presented to the St. Louis Medical Society a specimen of a cancerous mammary gland that had been removed by Dr. Gregory, by means of "arrows" made of chloride of zinc and flour.

THE CAROLINA SISTERS.

The two girls, united by the lower part of their backs, who have been exhibited almost from the time of their birth, are now in Boston, and a notice of them appears in the *Boston Medical Journal*. They feel hunger and thirst, and a call to evacuate the bowels or bladder simultaneously; neither one knowing whether her own organs or her sister's are being evacuated. Prof. Simpson states that when he saw them in 1856 the call to evacuate these organs was not contemporaneous. The attendant here, however, is quite sure that such is now the case, and that one stream of water only is passed. In regard to this last point, if there are two urethral orifices, as observed by Drs. Minot, Simpson, and Ramsbotham, and of course two bladders, it seems hardly possible that these last should be evacuated separately, if the connection between the two organs is such that the call is simultaneous; and, as to the fact, the subjects themselves may be mistaken, as well as the attendant. The connection is through the nervous system, but in the case of the intestines the organs themselves must unite not far above their termination, and this last is so sensitive a part that the call might very well be simultaneous, and it might often if not generally happen that neither individual would know whether the discharge was mainly from her own bowels or her sister's. Menstruation began when they were fourteen years old, and is in every way regular, but with some occasional pain, which is felt by the two. The breasts are well developed, and this is evident. The amount of menstrual fluid discharged at each period, and also the amount of urine that is evacuated, is not greater than it would be in the case of a single individual. Drs. Simpson and Ramsbotham state that there was a single vulva, with two vaginal orifices and two clitorides. That hunger and thirst should be experienced simultaneously when the digestive organs are almost entirely separate, and when the vascular connection must be so trifling, is certainly very remarkable. For some years they lay upon one side, and their heads in consequence became somewhat deformed; but they have since lain upon either side, though of course inclined more towards the back when upon the divergent side; and one may be talking and laughing with those about her whilst the other is sound asleep. Their general health is quite good, and the most severe sickness that they ever had was the fever and ague, when the chills were simultaneous and also the heat. One alone may have a slight headache, as from indigestion; but, if severe, it is felt by both. The effect of a cathartic upon one when given to the other the attendant knows nothing of, as since she has been with them one half of any such medicine has been given to each when required. Their weight within the last month was 170 lbs. M. was very much the smallest in early life, as above stated, and C. could raise her from the ground and walk off with her, but she has not done this for the last year or more, on account of the strain; M. having gained upon her sister, so that now the difference between them is not great. M., however, wears a boot that is one size smaller than C.'s. Having seen the girls several times, and finding that it would be entirely out of the question to get a vaginal examination, I requested the attendant to make one, with instructions; but, intimate as she is with them, she had no better success than myself. She had examined them, however, at some former period, and stated that the united vulvæ were no larger than they would be in a well-formed girl of their age, but that they were fairly beneath the pelvis, so as not to be visible when looked at from the front. There was also one anus, upon one side, and about one and a half inches from the vulvæ. The union has generally been said to be by the sacrum; but Prof. Lee has described it as extending to the lumbar vertebræ, and I should fully agree with him. It seemed, after observing the position of the lower ribs, and the ilia, as if the spinous processes of the third lumbar vertebræ might be in contact. When the lower extremities of either one are touched the other feels it, but she cannot so far locate the sensation as to say whether it is the foot or leg that is touched. There must be an intermingling of the nerves of sensation at the lowest part of the spine; and this would probably be explained, as Dr. Wyman suggests, by the fact that these nerves arise from the back of the spinal marrow, and might naturally blend, as the subjects are united by the backs; but the motor nerves, arising from the anterior columns, are not so connected that one of them can move the limbs of the other. The heart of M. has been positively stated to be in the right side of the chest; but I could not feel persuaded of this, though there is evidently some displacement. This last may, perhaps be owing to the distortion of the chest,

though nothing of the kind is observed in C. Vesicular respiration was heard upon each side of the sternum; and the second sound of the heart was about as loud upon the right side of the chest as upon the left, but it was loudest over the sternum.

ERGOT IN THE TREATMENT OF PURPURA.

Dr. Bauer, of Neutershausen (*Deutsche Klinik*), reports great success in the treatment of purpura hæmorrhagica with *secale cornutum*. He gives 8 to 10 grains three times, or oftener, daily, until hæmorrhagic manifestations cease. When anæmia remains he treats it with chalybeates.

A NEW TREATMENT FOR CHRONIC DYSENTERY.

Dr. E. M. Morse (*California Medical Gazette*) pursues the following method in treating this disease:—The diet is carefully regulated, and the patient kept in a recumbent position, to assist the return of blood from the mesenteric veins. At daybreak, on each alternate or fourth day, he gives a mild cathartic to clear the alimentary canal. After the aperient has acted sufficiently, he injects, very slowly, from two to four pints of Labarague's solution, in the proportion of one to twenty of water. As much of the injection is used as the patient can well retain. Each injection should be a little stronger, until the patient can feel a smarting or burning sensation. Should there be any tenesmus after the injection has passed out, he uses an opium suppository. The injection of the soda should generally be used once a day, though as the disease progresses favourably it may be given less frequently.

ON ACCOMODATIVE ASTHENOPIA.

Dr. J. G. Rogers, Madison, Ind. (*The Western Journal of Med.*), relates the following case of asthenopia: A lady, aged 30 years, when first seen had suffered for two years from asthenopia, to such an extent that the mere effort of fixing vision for a moment induced severe frontal pains, toothache, lachrymation, palpitation of the heart, and an intolerably nervous condition of the whole system, even pains in the lower extremities. Coupled with this was an inability to walk or make any marked exertion without the same exhibition of inability of the whole muscular and nervous system. Chronic metritis with retroversion, which had existed for several years, was the foundation of all this trouble. On examination of the eyes, a hypermetropia of one twenty-fourth was found. Number thirty glasses were ordered to be worn constantly, but no change was experienced. Thereupon the ciliary muscle was paralyzed by instillations of atropia, and it was found necessary to continue this for five months before the habit was obviated. Then the glasses were comfortably borne, and began to fulfil the indication of doing part of the work of accommodation, which, in ordinary cases, they will do from the moment of applying them. From that time to the present, two years, the irritability of the eyes has gradually lessened, and now the patient can read for a short time quite comfortably. The glasses are constantly worn, though at times they are laid aside without discomfort. By rational application of every possible means the nervous debility and its cause, the uterine lesions, were made to succumb, and now the patient expresses herself as enjoying a comparative elysium.

CONGENITAL ARTIFICIAL ANUS AT THE UMBILICUS.

Dr. A. S. Mayo (*Richmond and Louisville Med. Journ.*) reports a case of artificial anus at the navel, occurring in a female child seven days old. The cord had separated as usual, except that it had left an ulcerated surface, and from this surface both wind and discharges came. The child also passed stools by the natural anus. The artificial opening was cauterised freely, hoping in this way to excite adhesive inflammation, but this not accomplishing the object, the funis was ligated a second time. This had the desired effect, and recovery was perfect.

VAGINISMUS CURED BY BROMIDE OF POTASSIUM.

Dr. Raciborski publishes a case of excessive vaginismus which had existed for some time. It was accompanied with dysmenorrhœa. Bromide of potassium was prescribed, and the cure was rapid and complete.

ERGOT IN FACIAL NEURALGIA.

Dr. Campbell gives the following testimony of the efficacy of ergot:—"I have used it in a severe case of facial neuralgia, which had resisted quinine, morphine, and val. zinc, and found that sixty grains in infusion in three doses promptly arrested it."

NINE BONES IN THE CRANIUM.

Dr. W. J. Burge (*Leavenworth Med. Herald*) has been shown the skull of an adult, said to have been that of a negro, with a peculiarity of the occipital bone. From one and a quarter inches on each side of the junction of the sagittal with the lambdoidal suture, there is a perfectly distinct suture, the two meeting just above the occipital protuberance, and forming a lozenge-shaped bone. Dr. Burge inquires if this is the peculiarity of the skull of all negroes.

ATROPHY OF THE HEART.

The following general results are presented by Dr. N. Finn, of the Pathologico-Anatomical Institute of St. Petersburg, as having been derived from the examination of one hundred hearts. 1. Simple atrophy is never developed as the only morbid condition. It is unattended by a morbid condition of the cardiac blood-vessels. 2. Neither the absolute or relative weight of the heart, thickness of its walls, nor their reduced circumference, can be received as a certain indication of the presence of atrophy of the organ. 3. The brown atrophy of the heart, so called from a morbid change in the colouring matter of the muscular tissue, is a common accompaniment of all diseases attended with great emaciation. 4. Fatty degeneration of the heart (fatty infiltration) occurs chiefly in persons who have a large development of the subcutaneous adipose tissue; the infiltration is often to such an extent as to prove troublesome. 5. Fatty degeneration of the heart occurs as an acute or chronic affection. It is observed more frequently on the right than on the left side of the organ. In some cases the entire substance of the walls of the ventricle is affected, in others only a portion. In the chronic form there is always atheromatous degeneration of the cardiac blood-vessels. The *arcus senilis* is never met with in cases of fatty degeneration of the heart.—*Centralblatt f. d. Medicinisch. Wissenschaften*.

PREVENTION OF PAIN FROM BLISTERS.

M. Bricheateau states that he has found the hypodermical injection of from 5 to 10 drops of a solution of hydrochlorate of morphia (1 part to 50 of water), made immediately before applying the blister, a most excellent procedure. When the blister is good it begins to rise in from three to five hours, and, as the effect of the morphia lasts for six or eight hours, all pain is prevented during the process. In some persons, whose skins resist a blister more than ordinarily, the injection may be delayed for an hour after its application. By this means, when a blister is applied at night, the patient, so far as it is concerned, may still enjoy his night's rest; and sensitive persons are saved much suffering, as, for example, in the case of the application of blisters to the hypogastric region in young women. The dressing a blister also requires attention. No greasy substance should be applied; but having left as much of the raised epidermis intact as possible, this should be emptied of its serum by a broad clip with scissors, and, after it has sunk down again on the dermis, a thick layer of wadding should be applied. This is to be left on for two days, no other dressing being required. Cicatrization may also be hastened by the following contrivance:—Cut a good-sized hole in the centre of the blister before applying it, and this central untouched portion greatly expedites the healing of the denuded zone which surrounds it.—*Bull. de Thérap.*

SPINA BIFIDA; INJECTION OF IODINE; RECOVERY.

The rule is that these cases die. M. Roux, of Meximieux (France), has recently published in the *Bulletin de Thérapeutique* the case of a girl, six weeks old, presenting this deformity. The tumour hung from the extremity of the sacrum to the lower third of both thighs. The author first made an exploratory puncture, and removed about an ounce of limpid fluid. He tried then the following plan:—An assistant was desired to hold the tumour in such a manner as to occlude the opening into the spinal canal; the operator then injected an ounce of the following solution: Distilled water, eleven drachms; tincture of iodine, three drachms; and iodide of potassium, 180 grains. The liquid was left five minutes in the sac, the latter being kneaded with the hand of the operator. The solution was then withdrawn to the last drop by the exhausting agency of the syringe. This proceeding succeeded so well that, in a fortnight, there was only a hard nucleus left, no larger than a walnut. M. Roux attributes his success to the occlusion of the canal, and to the withdrawal of the very last drop of the injected fluid.

THE PHYSIOLOGY OF THE CEREBELLUM.

S. Weir Mitchell, M.D. (*Am. Jour. Med. Sciences*), during the last six years, has experimented chiefly upon birds, with reference to the physiology of the cerebellum, and the foundation for the following opinions rests upon experimental and other proofs peculiar to his own personal researches, and also upon a wide general consideration and study of the clinical history of cerebellar disease. The experiments made upon the cerebellum have extended over portions of at least six years. During this time he has ablated the cerebellum eighty-seven times, and performed more than 260 experiments upon the influence of irritants on this and adjoining organs. He is disposed to deny to the cerebellum any larger share in co-ordination than exists in any ganglion employed in voluntary motion, and to assign to it a part closely relating it in powers to the chain of spinal ganglia. The cerebellum becomes, therefore, a great re-enforcing organ, capable of being more or less used in volitional muscular motion. Its loss leaves no functional defect save some incapacity for prolonged motor activity. He finally adds, that while he believes the cerebellum to be one of the great centres of force-development for voluntary, and perhaps involuntary motion, he is not at all prepared to assume that it has no other function.

ON PHOSPHORUS POISONING AND FATTY DEGENERATION.

Wm. Pepper, M.D., in an article on "Phosphorus and Fatty Degeneration," recently published in the *Am. Jour. Med. Sciences*, states that phosphorus acts by entering the blood in the form of a highly irritant substance, and in the course of its excretion from the various glands induces a degree of irritation bordering on inflammation, attended with proliferation of cells, which are not fully organised and readily undergo fatty degeneration. The red blood-globules are dissolved by phosphoric acid as by the bile acids. The falling of the temperature of the blood, the echymoses of the serous membranes, the serous effusions stained with dissolved hematine, bloody urine, which are noted after its introduction, are all results of the same peculiar action. The manner in which this destruction of the red globules, which are the oxygen-carriers of the blood, favours fatty degeneration, is evident; and, when combined with the tendency which always exists in cells formed by unduly active proliferation, to undergo this change, appears to Dr. P. to afford a satisfactory solution of the extraordinary lesions met with in phosphorus poisoning. In conclusion, he alludes to the close similarity between the symptoms of yellow fever and acute atrophy of liver, and those of poisoning by phosphoric acid, taken in connection with the fact that the bile acids resemble it closely in their action on the blood.

NEW METHOD OF TREATING THE PEDICLE IN OVARIOTOMY.

(EXTRACT from an article by J. F. MINER, M.D., in the *Buffalo Med. and Surg. Journal*.) I have proposed for myself, and desire to suggest to others, a plan of separating the tumour from its attachments to the pedicle which appears to my mind as feasible, at least in some instances, and, where practicable, as having decided advantages. A few months since I was invited to remove an immense ovarian tumour occurring in the person of Mrs. Foster of Cattaraugus county, N. Y. It was of years standing, had been repeatedly tapped, but at length the contents proved too thick to be drawn through the largest size canula, and the distress becoming too great for endurance, any operation which would end it whatever might be the result, was gladly accepted. The tumour was multilocular, very large, weighing, as near as could be ascertained, between seventy-five and 100 pounds. It was attached throughout its entire circumference to the omentum, intestines, walls of the abdomen, and all other parts in which it came in contact. These attachments were not so firm but that they could be broken up, and with great care the tumour was separated from the surrounding parts until the pedicle was reached. The process of enucleation had been carried on so extensively and successfully that encouragement was afforded for continued trial; the pedicle was large and extended over a wide surface, but by gentle and patient effort it was separated from its entire attachment to the tumour, and the immense growth removed without the ligation of a single vessel. The terminal branches of the vessels of the pedicle gave out no more blood than issued from the vessels of the attachment elsewhere. All hæmorrhage soon ceased, and the incision was closed by interrupted suture.

The success of this procedure was complete, and the patient

continued for more than two weeks without an untoward symptom, and her recovery seemed almost certain. She then commenced to lose her relish for food, grew weak and desponding, and died from exhaustion on the twenty-first day after operation. This fatal termination detracted nothing from the success of this mode of treating the pedicle; indeed, so remarkable was the size and attachment of the tumour that any attempt at recovery is surprising, and yet the patient continued to improve long enough to show that the operation was at least in her case unobjectionable.

OSSEOUS REGENERATION OF STERNUM.

DR. ENRICO BOTTINI communicates to the *Annali Universali di Medicina* the particulars of the case of a soldier, æt. 30, wounded in the superior region of the sternum during the Italian campaign of 1866. The ball lodged, producing caries, necessitating an operation for its removal which exposed the pleural sac, the osseous walls of the sternum having been gradually absorbed, and a prompt recovery ensued, and new osseous tissue was formed analogous, in resistance to the touch, to the rest of the sternum.

THE INTRODUCTION OF THE CLAMP IN OVARIOTOMY.

MR. T. SPENCER WELLS writes as follows to the editor of the *Boston Medical and Surgical Journal*, in reply to a letter from Dr. Parks, inquiring who was entitled to the honour of having invented the clamp used in his operations in ovariotomy:—

"The credit of the introductions is due to Mr. Hutchinson, Surgeon to the London Hospital. He first used one in 1858. It was simply the common calliper of carpenters, which he used and left applied, handles and all. Then the handles were made movable, so that they could be taken off as soon as the clamp was fixed. Then I made the blades parallel, and did without handles. But I afterwards returned towards the original form of clamp, altering the joint and the form of the opposing surfaces of the clamp until I arrived at that which I now use. You may see it figured in Druitt's *Vade Mecum*, ninth edition, 1865, page 541. I have now (January 25, 1869,) completed 300 cases. Of the

1st 100 cases, 64 recovered and 34 died.

2d 100 " 72 " " 28 "

3d 100 " 77 " " 23 "

Total 300 " 213 " " 85 "

A general mortality of 28 per cent., but it is very encouraging to note that the mortality has been steadily diminishing with increasing experience."

Since October last he has completed the operation of ovariotomy in 36 cases. Of the thirty-six women, 31 recovered and 5 died: and it is a remarkable fact that in every case in which the pedicle was long enough for him to use the clamp the patient recovered.

MEATH HOSPITAL, DUBLIN.

THE operation of lateral lithotomy was performed on Monday morning last, in the Meath Hospital, by Mr. R. St. J. Mayne. The patient was a boy of five years of age, and the calculus, weighing 35 grains, of a globular form, and of twelve months' standing, was removed without accident. We hope to publish a full record of the case in a future issue.

THE reported "serious illness" of the Premier proves to be but gossip. From a reliable source we learn that the right hon. gentleman is somewhat indisposed from the excessive fatigue and anxiety of the present Parliamentary Session, but that with a few weeks' mental and physical relaxation his medical advisers anticipate a complete restoration to health and strength.

LAST WEEK we had the pleasure to announce the munificent bequests to various charities of the late Dean of Durham. Mr. Titus Salt has since followed his example, by presenting to the Royal Albert Asylum for Idiots and Imbeciles, for the North-east Counties, now being erected at Lancaster, the munificent sum of £5,000.

A CHEMIST AND DRUGGIST named Miller, of Bow, has been committed for trial for having signed and delivered a false medical certificate, contrary to the provisions of the Vaccination Act.

Medical News.

UNIVERSITY OF LONDON.—The following is a List of the Candidates who have passed the recent First M.B. Examination:—

Ball, James Barry, University College.
Burn, William Barnett, St. Bartholomew's Hospital.
Carr, William Ward, University College.
Carter, Alfred Henry, University College.
Edeger, Ebenezer Rust, B.A., University College.
Elkington, Ernest Alfred, Queen's College, Birmingham.
Harding, Alfred William, B.A., University College.
Harris, Michael, Guy's Hospital.
Hayes, Thomas Crawford, B.A., Dublin, King's College.
Ingoldby, Joseph Theodore, Guy's Hospital.
Jones, Thomas, Guy's Hospital.
Southee, Henry Edward, Guy's Hospital.
Warner, Francis, King's College.

SECOND DIVISION.

Buckley, Samuel, Royal Manchester School of Medicine.
Humphreys, John Henry, Sydenham College, Birmingham, and University.
Hunt, Thomas Henry, Royal Manchester School of Medicine.
Perkins, Charles Edward Steele, Guy's Hospital.
Petch, Richard, King's College.
Pope, Harry Campbell, Liverpool Royal Infirmary.
Scott, Peter Thomas, Guy's Hospital.
Skrimshire, Frederic William, King's College.
Stanger, William, Guy's Hospital.
Westcott, William Wynn, University College.
Wood, Robert Arthur Henry, Liverpool School of Medicine.
Yate, Edward, St. Bartholomew's Hospital.

PHYSIOLOGY ONLY.

FIRST DIVISION.

Baach, Fletcher, King's College.
Burgess, Wm. Frederick Richardson, Guy's Hospital.
Gibbins, Alfred Thomas, King's College.
Smith, Arthur William, Guy's Hospital.

SECOND DIVISION.

Joubert, Charles Henry, St. Mary's Hospital.

EXCLUDING PHYSIOLOGY.

FIRST DIVISION.

Owen, Edmund Blackett, St. Mary's Hospital.

SECOND DIVISION.

Betts, Arthur Raymond, Guy's Hospital.
Branfoot, Arthur Mudge, Guy's Hospital.
Davison, William John, College of Medicine, Newcastle-upon-Tyne.
Eardley-Wilmot, Robert, King's College.
Moss, Herbert Campbell, King's College.

MEDICAL CLUB.—The usual monthly dinner took place at the Club on Wednesday last. Mr. Edwin Saunders occupied the chair, and among those present were Dr. Billing, Mr. Clover, Mr. Forsyth, Mr. Balmanno Squire, Mr. Parkinson, Mr. Critchett, Mr. Wright, Mr. Harrison, Dr. Cholmeley, Dr. Power, Mr. Henry Smith, Dr. Swettenham, Dr. Taylor, Sir W. Fergusson, Bart., Sir Charles McGrigor, Bart., Dr. Evanston, Sir Ranald Martin, C.B., Mr. Field, Mr. John Galton, Mr. H. Bigg, Dr. Mackie, Mr. W. Adams, Dr. Peter Allen, Dr. Tatham, Dr. Smart, C.B. The next dinner will be the last of the present season, and will take place on Wednesday, August 28th, on which occasion Dr. Lory Marsh will preside.

THE NEW INFIRMARY AT KIDDERMINSTER.—The carpetweavers of this town lately held a *picnic* and picnic, handing over the proceeds, amounting to £150, to the building fund of the new infirmary.

TESTIMONIAL.—On the 27th ult., a handsome testimonial was presented at the twenty-fourth anniversary dinner of No. 1867 Court of Foresters, to Mr. John Angus, surgeon, of Frith street, Soho, Medical Officer, Strand Union, in recognition of his valuable service to a large body of the members of that institution. The testimonial consisted of a handsome and classically-designed tea-urn.

DR. ARMSTRONG, R.N., Director-General of the Medical Department of the Navy, on Wednesday left the Pier Hotel, Southsea, for the Admiralty, on his return to London, after having made a minute official inspection of the naval medical establishments at Portsmouth and of Her Majesty's ships in the port.

LIME JUICE.—In the House of Commons on Thursday, Mr. Candlish asked the Secretary to the Admiralty if the Controller of the Victualling Department or other officer had reported favourably on the use of lime juice without the addition of 15 per cent. of spirits; that pure lime juice had been sent to the tropics and returned in perfect condition; and that the addition of spirits reduced the antiscorbutic properties of lime juice; and if he would lay any such report or reports upon the table of the House. Mr. Baxter replied that three of the principal officers of the Victualling Department had reported favourably on the use of lime juice in the Navy. He held in his hand their report, which he would lay upon the table.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

MR. ROBERT RICE, Much Woolton.—Dr. Kirby's Portable Dispensaries can be obtained at the manufactory, Newman street, London. The book "On the Ready Administrations of Remedies," of Mr. Renshaw, 256, Strand.

MR. F. M. BETTY, Walsall, inquires "If a gentleman who has practised as a chemist and druggist for nine years, and subsequently becomes qualified and registered as a medical man, can he still continue an open shop?"

To this we can only reply by quoting the law as laid down in the Amended Pharmacy Act of 1868. Clause 1 says:—"From and after the 31st day of December, 1868, it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title 'Chemist and Druggist,' or 'Chemist, or Druggist, or Pharmacist, or Dispensing Chemist, or Druggist, in any part of Great Britain, unless such person shall be a Pharmaceutical Chemist, or a Chemist and Druggist within the meaning of this Act, and be registered under this Act, and conform to such regulations as to the keeping, dispensing, and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." Clause 3 says:—"Chemists and Druggists within the meaning of this Act shall consist of all persons who, at any time before the passing of this Act, have carried on, in Great Britain, the business of a Chemist and Druggist, in the keeping of open shop for the compounding of the prescriptions of duly-qualified medical practitioners, also of all Assistants and Associates who, before the passing of this Act, shall have been duly registered under or according to the provisions of the Pharmacy Act, and also of all such persons as may be duly registered under this Act." Further on at Clause 25, we have it that "Persons registered under 'The Medical Act' shall not be or continue to be registered under this Act."

Our correspondent will see the Act is somewhat ambiguous, and that is one reason why the Pharmaceutical Society do not often enforce the latter provision, although legally they could do so. This Act does not apply to Ireland.

A SUBSCRIBER, Dublin.—We regret that it will not be in our power to publish the proceedings of the Dublin Pathological Society for the 12th of April. The Council of the Society have responded to our repeated offer to publish the proceedings by interposing hindrances which make it almost impossible for us to do so. The official record of the transactions of the Society, which is supplied to another periodical without charge, is refused to us, and is thus deferred for three months, until all interest in it has ceased to exist, then to be circulated to one-third of the number of readers which the MEDICAL PRESS AND CIRCULAR enjoys. We propose once again to repeat our request to the Council of the Society at the opening of next Session.

BOOKS RECEIVED.

State Medicine, Resolutions and Report of the Committee appointed by the General Medical Council.

Hooping Cough, Its Pathology and Treatment. By P. Martyn, M.D., B.L. London: John Churchill and Sons.

Sanitary Report of the District of Paddington. By Dr. W. Hardwicke. EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 50.)

CONTINUED FEVERS.

THE forms of disease classed under the head of continued fevers include attacks of all degrees of severity, from the ephemeral paroxysm of pyrexia to that low, tedious, and exhausting malady which, having reduced the vital powers to the lowest ebb compatible with life, finally destroys them in a period varying from twenty to thirty days, or leaves the patient so debilitated and predisposed to recurrences of the same or other affections, that convalescence is not only tedious, but liable to numerous interruptions. In former times, and as probably is still the case, fever of the continued type prevailed to the greatest extent during the dry season. Young soldiers were especially liable to its attacks, so much so, that very few altogether escaped being subjected to it within the two first years of their residence in India. Its attacks are most common from March till October, both inclusive, and in one form or other occasions the greatest number of admissions into hospital of any disease met with in regimental practice; although not only is the mortality occasioned by it considerable as compared with other endemic diseases, but remarkably so as compared with that of continued fevers in the United Kingdom. Thus, according to the documents to which I have had access, there were in the 10th Foot 4,044 admissions by this fever among soldiers, of whom 123 deaths, or a ratio of mortality to cases equal to 2.79 per cent.; among officers there were 218 admissions and 2 deaths, or 0.91 per cent.; among soldiers' wives 332 admissions and 10 deaths, or 3.01 per cent.; and among children, 156 admissions and 19 deaths, or 12.18 per cent.

Here we see that in this, as in other diseases already noticed, the rate of mortality varies according to class. In the present instance it is shown to have been greatest among children, next among women, then among men, and least among officers; while, according to statistics, officers suffered in greatest proportion from its attacks, next men, then women, and least of all children.

Several years ago I had occasion to allude to the increase in this disease, as well as of others, among regiments in India, caused by what really was intended to be an act of liberality and consideration by the Government of that country. I then expressed myself as follows:—

"It is painful to consider that the rewards sometimes given by a liberal Government, to troops who have been the means of bringing a campaign to a successful termination, may themselves prove a fertile cause of fever, as well as of some other diseases, claiming nearly as many, if not a quite equal number, as those who may have fallen honourably on the field of battle. For instance, the 10th Regiment, in the action at Sobraon, on the 10th February, 1846, lost in killed 29 men, in addition to 136 wounded, of whom six subsequently died in the Regimental Hospital. During 1845-46, the deaths from fevers of all kinds were 21. In the succeeding year—namely, 1846-47—the fatal cases of fevers amounted to 53, and of this number 40 occurred during the months of July, August, and September.

"In reference to this great mortality, we find, in the Hospital records, that suspicions were entertained that the drunkenness and exposure must have had a share in the sad work of destruction, as it was about this period that the Government donation batta (for Sobraon, &c.) was distributed. If, then, in this instance the supposition be allowed that of the 53 deaths that took place from fever in the 10th Regiment one half were solely attributable to the endemic influences which seem, in other seasons, to have given rise to the malady, it may, with equal propriety, be believed that the other half were occasioned by the drunkenness in which the men were enabled to indulge by the distribution of batta.

"The fact becomes, therefore, worthy of attention, that while the number of killed among one regiment at one of the most sanguinary of our Indian battles was only 29, no fewer than 26 lost their lives by only one form of disease, which more or less directly originated in consequence of the pecuniary rewards given for their services on that occasion."

I may observe, with reference to this matter, that not only in India, but at home, have I observed very serious evils to follow upon the issue of batta and other pecuniary donations to soldiers. Drunkenness and excesses of various kinds invariably follow upon such occasions; sickness and violence, whether accidental or intentional, destroy several lives; the health in other instances becomes permanently injured; crime is rampant, and men, some with families, who have for years led exemplary lives, and obtained promotion as the fitting reward, are, in an evil hour, led into temptation, the result of which is their own ruin and the after poverty and misery of all dependent upon them. From considerations such as these, I would therefore urge the desirability—nay, actual necessity—of abandoning the system of issuing to soldiers, who, with few exceptions, are improvident, sums of money which only afford them the means of injuring themselves morally and physically. It is right that certain rewards should be conferred upon men who have undergone the hardships and dangers of a campaign, but it is no less desirable that these rewards should not be made the means, by destroying discipline for the time, of impairing the efficiency of the service. Could both ends not be attained, then, by the institution of regulations under which batta, prize money, volunteering money, and all other casual allowances should be paid into a fund bearing interest, and only be at the personal disposal of the individual on his discharge, or under such restrictions as might be determined upon?

The usual manner in which an attack of continued fever occurs is something like this:—A soldier, probably young, of short residence in India, robust, and otherwise in good health, is brought to hospital suffering from ardent pyrexia, increased temperature of the surface, flushed face, throbbing headache, and so on. For two or three or more days he has felt "a little out of sorts;" has been unable to take his meals; has had an inclination to vomit, with "flying" pains here and there, but especially in his limbs and loins; and these symptoms may have manifested themselves without sufficient evident cause, or, what is far more frequent, have succeeded to the simple exposure to the sun or exposure after drinking rum or native spirit—being subjected to wet, and then having to remain for a time without a change of clothes—or exposure to a chill at night; and this last circumstance frequently happens as the hot season is setting in, or is about to give way to the cold. In either case the days and evenings are so warm that the soldier in India is induced to take his bed from his barrack room, and sleep either altogether outside or in the verandah. At first he is unable to bear much clothes upon him, and thus falls asleep. Towards morning, however, the cold increases, and by and by awakes him; he finds himself chilled, and at last, after repeated exposure in this way, is attacked with fever with or without catarrhal symptoms.

It may be proper here to observe that, while sleeping in the open air (in India) renders a person liable, during certain seasons of the year, to attacks of catarrh, continued fever, or ague, yet the prevalence of the habit among those who have been long in the country induces me to believe that during other seasons, especially the hot winds, when hardly any moisture exists in the atmosphere, not only is it unattended with danger, but is actually beneficial.

For three months in the year the heat of the air is such that persons who have not themselves experienced it cannot conceive its intensity. Within doors, the ordinary contrivances employed for cooling it will reduce the temperature of a room to 87° F., while the thermometer outside exposed to the sun will range above 140° F.; so that the sensations of a person on first going into an apartment so cooled are probably about what a Russian experiences when he throws himself from his warm bath into snow.

Soldiers, however, have not the art, neither have they always the means, of thus lowering the temperature of their barracks, the walls of which speedily become heated to such a degree that the sensations are oppressed on going near them, and anything seems preferable to sleeping in such an oven. Nor do I think it would be advisable in any way that they should be forced against their will to remain inside.

In some parts of the world, where the land wind surcharged with the germs of disease sweeps over unhealthy swamps, and comes loaded with pernicious matters, blowing from evening till sunrise, it would be madness in any person to sleep out of doors, and most improper in officers to permit such a habit among troops. Neither can it be practised in many parts of Lower Bengal without risk; but away from lakes or swamps, with a clear dry atmosphere, as in the upper provinces of India, these objections do not hold good.

The more I have seen of diseases affecting the general system, such as fevers, the more am I convinced that their characters vary according to locality. Nor ought this fact to be forgotten in the management of cases that come under our observation. So long as the febrile action continues ardent and uncomplicated with any particular amount of local deterioration, we have in common continued fever little to fear; the attack will in all probability wear off in a short time, leaving no other effect than a little temporary debility. But let us beware of those cases where particular affections of the viscera of either of the large cavities become implicated, or where, with or without treatment, the first symptoms speedily give place to those of debility or collapse; and let our treatment be so directed that, while our measures are employed with a view to subdue the febrile symptoms, we may, nevertheless, keep the case in hand, so to speak, as to be ready to combat whatever tendency it may assume, to change or modify its original character.

In the treatment of this very prevalent disease we must be cautious, in administering even the lowering medicines that are indicated, lest their effect should be to induce a state of weakness or complete collapse, from which much difficulty may be experienced in recovering the patient.

Cold effusion is a remedy equally valuable during the continuance of ardent pyrexia in one fever as in another; and the gratefulness of the measure to the sensations of the patient, and its powerful effect in inducing a remission, followed by refreshing sleep, ought always to be borne in view.

After the first intensity of the pyrexia has given way, and the pulse become reduced in frequency and force, the skin cool, and the patient has perhaps fallen asleep, it is essential in all cases, even the most trivial, that caution be exercised in the degree to which lowering medicines are pushed; and in order to guard against dangerous depression, it will be necessary carefully to watch the case, in order that the first tendency to such exhaustion may be combated by appropriate remedies.

When such a tendency does manifest itself, a combination of quinine, ether, and camphor will generally be found to be the most useful remedy in restoring the normal state of vital action, and in diminishing what disposition may still remain to febrile attack. It is impossible to lay down definite rules as to the proper interval between the doses, or the length of time a particular remedy ought to be continued; but a repetition of the above every hour until a definite effect is produced, increasing the intervals while necessary, may, perhaps, be deemed the most appropriate instructions in such a case.

It frequently happens in cases of fever, as occurring in India, that a degree of debility remains, after the disappearance of the primary disease, altogether out of proportion in degree to what might be expected from the severity in the first instance. Tonics, nourishing diet, wine, or spirits must, therefore, be given according to the necessities of individual cases; and it will be well if we learn early in our military practice not to treat all our patients, whose diseases are referable to a certain head in our returns, upon

one principle of routine, for in no class of affections so much as in fevers does it become necessary that we should not be blindly led by school and theoretic impressions, but should learn to think for ourselves, and make allowances for individual peculiarities, the nature of the prevailing disease in particular years and in particular localities.

During convalescence, mild tonics, a weak mixture of quinine, or decoction of cinchona, with a moderate allowance of wine or beer, and light nutritious diet, form the most appropriate measures. We ought to be cautious in permitting the patient to get out of bed too early, in order to avoid the danger of a relapse; but when this may be permitted, gentle airing, as in a dooly, will be beneficial.

I am not aware of any point in the treatment of fever in India on which it is necessary to caution the young medical officer so much as on the administration of stimulants. Bringing their home opinions with them, it is by no means uncommon to find them in all cases of fever, even in the ardent remittent, giving large quantities of wine during the continuance of high states of pyrexia; and in such, as might be expected, the danger that always exists of the disease becoming transformed into heat apoplexy is increased, at the same time that the proper opportunity is lost for employing the more appropriate remedies.

Indeed, the employment of diffusible stimuli in early stages of the affection, while inducing excitement of the powers for a time, would seem either to increase whatever tendency there may be to cerebral affection, or at least protract the period of pyrexia.

It is not intended by these remarks to deny the utility of wine in the cases under consideration. All that is desired is to inculcate the necessity of caution in its use. In the great majority of instances, however, we find that the employment of beef-tea, jugged soups, with the usual tonics, will be sufficient until the commencement of convalescence, after which much discrimination is necessary in directing the further progress of the patient towards complete recovery.

Fevers of the typhus or typhoid type are, and have always been, very rare among British soldiers in India. The presence of both these diseases, however, has been observed and reported by army surgeons many years ago, although, on account of cleanliness and free ventilation observed in barracks and cantonments, no more than seven cases of the former affection appear to have been noted in the statistics of the 10th Regiment during thirteen years in that country, and they occurred while the corps was quartered in close unsuitable places in Lahore, immediately subsequent to the first Punjab war. According to statistics of the corps, one case occurred under these circumstances in 1847-8, one in 1848-9, and five in 1850-1; and, although information is somewhat scanty in regard to the conditions under which the men were at the time placed, the following remarks by the surgeon at that time may even still have considerable value:—

He states that, at the commencement of the hot season (of 1847), when the regiment occupied the places just mentioned, numbers of men were driven into hospital by an endemic fever of the continued and remittent type. Its invasion marked by great prostration of strength, rigors, and flushings, succeeded by augmented heat of the surface, increased external action, and aching pains all over the body.

When taken in time it yielded rapidly to moderate depletion, antimonials, and quinine. The fatal cases were not numerous from this cause, and generally resulted in typhoid symptoms.

This last remark would naturally lead to the belief that the cases returned as "typhus" do not in reality represent the degree to which such prevailed; and it must be confessed that more extended and minute statistics than are in my possession must be supplied before the actual prevalence of typhus fever among our troops in India can be ascertained.

(To be continued)

ON LEADING ARTICLES IN THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.*

By ARTHUR LEARED, M.D.

THE remarks which I am about to make are not offered hastily, nor without consideration. When it is stated that they refer to the conduct of the Journal of the Association, I wish to add that they have no personal bearing. No one is more ready to admit than I am the great ability with which our late editor performed the arduous task entrusted to him. In some respects the Journal became in his hands a model of what such a publication should be. I also bear willing testimony to the able manner in which, under the present management, his labours have been continued.

Nevertheless, I feel convinced that the system under which our Journal is conducted is in some respects erroneous. My views, if carried out, would make the editorial work easier, and less invidious because less responsible.

Not a century ago the "leading article" was a thing unknown. Newspapers confined themselves to that which accorded with their original intention—the dissemination of news. The fourth estate was as yet no power. No one dreamt of the gigantic proportions which it presents today. But faithfully and well as this fourth estate has in many respects performed the high functions which it has assumed to itself, it may be fairly questioned whether the advantages it confers compensate for the great drawbacks entailed by the adoption of a system which seriously interferes with free thought.

Every public event, whether of a domestic nature, or involving relations with foreign countries, before the era of "leaders," necessarily exercised the faculties of readers, because they even left no alternative but to think for themselves. But a lazier and less healthy method now prevails; men pay other men to think for them. The organ through which these paid men give their utterances becomes a tremendous force, insensibly swaying the minds of multitudes. The newspaper does not merely reflect—but it leads public opinion. Hence it is that in the ordinary meetings of men, we do not hear them speaking their own thoughts, or stating their own conclusions, but speaking and explaining the thoughts and conclusions put into their mouths by their daily paper. We can indeed generally say of one that he is talking from the *Times*, of another from the *Standard*, or of a third from the *Daily News*, and so on, with perfect confidence, although it may be that the speaker himself, from the habitual practice of adopting ready-made ideas, is quite unconscious of the fact.

Now, whatever difference of opinion may be entertained about this kind of action of one mind upon many, in ordinary political matters, I think it will be conceded that there are other circumstances in which it must be pernicious.

I contend that no one man or set of men should be constituted as the anonymous mouth-piece of this great Association. The conviction has been forced upon me that we are pursuing a wrong course.

The British Medical Association now numbers more than 4,000 members, and the *British Medical Journal* is its accredited organ. In a certain sense the editorial statements made in the Journal are sanctioned by this great body of educated men. To guide these statements fairly, to be always just, would require an unerring instinct, scarcely human. It is one thing to write ably and with spirit, and another to be always impartial. It is notorious that our profession is pervaded by a spirit of clique, and how rare is it that a man is not open to some whisper of friendship, of dislike, or of self-interest? I speak openly, because the subject demands it. In the very ability with which our Journal is anonymously edited, lies the danger. A stupid article, no matter what its purport, is compara-

* The Author was prevented by circumstances from bringing this subject before the Leeds Meeting at the proper time. He prints this now because he believes it to be opportune to do so, and he has no motive but to elicit discussion on an important matter.

tively harmless ; but no article, however able, should be admitted, to the possible perversion of what is just, or one which is contrary to the views of a majority of this Association. I say this, because a majority should not in this matter rule the minority,—unless, indeed, it can be maintained that the Association exists for the Journal, and not the Journal for the Association.

In general politics questions are treated by the organs of respective parties from their different standing points, so that what is said on the one side may thus be compared with what is said on the other. The distortions of each may in this way be in some measure rectified by him who will take the trouble. The smaller field of medical politics affords the same opportunity, quite independently of the *British Medical Journal* ; no want is therefore supplied by its interference in that direction.

This leads to another grave consideration. Is it proper or consistent with the dignity of this great Association, represented as it is by the Journal, to descend, as it has descended, in that representative, into the arena of small animosities, or of mere personal feeling? What in the political world takes the name of party, in the more restricted medical world degenerates into clique. We have already seen too much of the result of this, and it is only possible, I submit, because the anonymous leading article is allowed to exist.

Once more let me remind you that virtually the Journal speaks in the name of the Association. That, at all events, is the light in which its utterances are regarded by a large number of readers, a wide difference therefore exists, in this respect, between our organ, and a purely political organ. The party which a political Journal represents is an unknown quantity, and its proprietary is anonymous. Antagonism is the life and soul of such a Journal. The plant grows in congenial soil, and is cultivated for the profit it yields. With us, on the contrary, this antagonism is a noxious weed, and should have no place. There is another error into which the Journal ought not to fall, but which it has not escaped, it ought never to become a partizan. It is indisputable that any man who seeks for an office, or is charged with a fault, will have his cause unduly strengthened, or else unduly damaged, by the editorial comments of the *British Medical Journal*. If the exact line between what is just and what is unjust could be always observed, this would be desirable. But it is impossible to observe this, for in such matters there is seldom unanimity of opinion, and yet an anonymous writer will exercise a more powerful influence than the same writer could effect in an ordinary Medical Journal.

All readers may understand the connexion between the Association and their Journal, and yet a large proportion of them will not duly estimate the bearings of this in a given case, but will assume that because it is sanctioned by the one it is sanctioned by the other. An old maxim has it, "Give me the writing of the people's songs, and you may write their laws." So it may with truth be said of this Association, "Give me the writing of your leading articles, and I will direct your counsels." It is, indeed, not too much to say that a clever editor may in this way come virtually to rule over the entire Association.

Great advantages have unquestionably resulted from the organization of this influential Association. In a social point of view this is especially the case. The local meetings throughout the country, as well as the annual gathering which we are now celebrating, are of immense use in bringing us together under agreeable circumstances. We thus come to know more of each other than would otherwise be possible, and we come also to be more and more convinced—that in unity lies our strength.

Nevertheless, how often is not something like the following spoken amongst us? What after all has the Association done to advance professional knowledge, which is commensurate with its organization and its large means?

The truth is that the field of usefulness which lies open to it in certain directions has scarcely been entered upon. The admirable report of the Edinburgh Committee on the

secretion of bile shows how much may be effected by the judicious encouragement of such labours. Records of this kind give a lasting value to the Journal far transcending that which the most able anonymous writing could give. It may be, then, that the Journal at present not only occupies too prominent a place in our minds, but absorbs too much of our funds.

To return to leading articles—it is a question whether the space they take up would not be better filled by fuller reports of the branch meetings of the Association, and with professional papers, for the admission of which there is a constant pressure. But if leaders must exist, let them be signed by their respective authors. By this means their injurious results will be, in a great measure, prevented. The system of signing such articles has long prevailed in France. In many periodicals in this country, the articles are also signed, and the practice is gaining ground. That the reasons for adopting it in the case of our Journal are more cogent than ordinary I have already endeavoured to enforce.

DISLOCATION OF THE ATLAS FORWARDS, WITH FRACTURE OF THE ATLAS, OCCIPITAL, PARIETAL, AND TEMPORAL BONES.

By JAMES RIDLEY, L.R.C.S.I., L.K.Q.C.P.I.,
East Dispensary, Liverpool.

I AM induced to bring the following case under the notice of the Profession from its extreme rarity and the few symptoms of importance exhibited, notwithstanding the serious injuries received :—

Thomas Walsh, a labourer, aged twenty-six, residing at Rose-place, stated that, on the morning of the 6th of July, as he was proceeding to his work, in company with another man, he received a blow which caused him to fall, the back of his head coming against the coping-stone of the pathway. He was slightly stunned, but went on to his work, which he was obliged to leave in an hour's time, as his stomach became ill. On arriving at home he was violently purged and vomited ; a slight discharge began to ooze from his ears. In consultation with my friend Dr. Birney, I visited him that evening, and found him perfectly sensible. He complained of general headache, pain in the neck, and slight difficulty in swallowing, accompanied by nausea, a thin sanguinary discharge from both ears ; and stated that he vomited blood twice during the day.

On examination, we found a deep sulcus between the atlas and occipital bones, when we concluded that there was a dislocation with fracture of base of skull.

Ordered head to be shaved, and an evaporating lotion to be applied, and a pill containing—

Calomelanos, gr. iij.
Pulv. antimonalis, gr. ij.
Ext. hyoseyami, gr. ss.

To be taken every third hour.

Pulse 60 ; pupils natural.

July 7th.—Slept during the night ; complaining of headache and difficulty in swallowing ; the discharge from ears still continuing. Pulse 68, weak and intermittent ; pupils natural. Ordered lotion and pills to be continued ; the face to be bled forwards on the chest.

8th.—Complaining of headache and occasional pains through the body and limbs ; the sanguinary discharge from ears still continuing ; nausea and difficulty in swallowing ceased. Pulse 80 ; pupils dilated. Ordered medicine to be continued.

9th.—Slept well during the night ; complaining more of the headache, and for the first time appears confused when spoken to ; the discharge from the ears increased in quantity ; still retaining the perfect use of his limbs. *Pupils insensible to light for first time.*

5 o'clock p.m.—Was suddenly seized with a convulsive fit, and rendered insensible until 4:45 the following morning, when he recovered his senses for a short time, wanting

to go down stairs, but was restrained, when he was again seized with a fit and expired.

By direction of the Coroner, in conjunction with Drs. Harris, Hanbury, and Birney, I made a *post-mortem* examination, and found a dislocation of the atlas forwards, with fracture of the posterior arch of that bone, fracture of the occipital, parietal, and temporal bones.

My principal reason for noticing this case was the total absence of paralysis until a few hours before he expired, having had no affection of the bladder or rectum up to time of his death.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

MR. PORTER'S CLINIQUE.

Nævus cured by Injection of Carbolic Acid.

MR. PORTER exhibited to his class a child named Margaret B., aged ten months, who had been received into hospital, about six weeks previously, for the treatment of a large nævus, situated on the lower part of the forehead, immediately above the nose. It was venous in character, and when first seen was circular in form and as large as half-a-crown, projecting forwards considerably. He resolved to attempt its solidification and cure by the injection of carbolic acid, and accordingly two minims of pure acid were introduced into the nævus by means of a hypodermic syringe. Such inflammation as followed having been allowed to subside, the operation was repeated, seven times in all, an interval of several days being permitted between each injection. No untoward consequences took place; the skin was not injured; and now, after the seventh operation, the mass had become solidified, and would in due time be absorbed.

Enlargement of a Mouth previously contracted by the Operation for the Cure of Hare-lip.

Mr. Porter also drew attention to a boy, aged twelve years, who had been operated on by him, about a fortnight before, for the purpose of enlarging his mouth, which had been lessened in size to an inconvenient and unseemly degree, by an operation for the cure of a hare-lip, which had been performed upon him in his infancy. He had made an incision at each angle of the mouth, extending outwards for about a quarter of an inch on either side; he then stitched the skin and mucous membrane together above and below. The wound healed rapidly, and the result, as now seen, was most satisfactory; the boy's mouth, which was before operation merely a circular aperture, was considerably enlarged, and improved in appearance.

Bloody Tumour of Scalp treated by Free Incision.

Under the care of Mr. SMYLY.

James Y., a healthy man, æt. fifty-six years, was admitted into the Meath Hospital on the 6th July, suffering from an extensive effusion of blood beneath the scalp, which had been caused by direct violence. The tumour, which was about two inches in diameter and of considerable depth, was situated over the left parietal bone. The great amount of blood effused, and the general condition of the parts, causing Mr. Smyly to dread that suppuration would ensue, he resolved to give exit to the effused blood. He accordingly made a free incision down to the bone, and squeezed out all the clots which were present. Some smart

arterial hæmorrhage followed. The edges of the incision were then brought into apposition, a narrow strip of lint soaked in carbolic acid was applied to their junction, and over all a compress and bandage was placed. Three days afterwards bad symptoms set in, and the man appeared in a sinking condition. The compress was removed, poultices were applied, the man rapidly improved in condition, and in a week was sufficiently recovered to leave the hospital.

This case is worthy of notice, inasmuch as the usual practice in Dublin hospitals in such instances differs from that pursued by Mr. Smyly, who cut into the tumour, instead of, as is generally recommended, carefully avoiding any incision whatever.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 132.)

Sir, I can use no language stronger in proof of this than Dr. Kidd's own. After admitting that the mortality of the Coombe, for the last fifteen years, has been 1 in 65=730; and ascribing the occurrence of metria, to a large extent, to epidemic influences, he goes on to say—"But let it not be supposed, when he spoke in this way of individual causes of the disease, and of epidemic causes, he for one moment doubted the influence of contagion. On the contrary, he believed contagion was a most influential cause of it, that the disease was highly contagious, and that if they were to prevent it, they could only hope to do so by directing their attention to this. Dr. Madden had told them just now, that he never saw two patients ill of puerperal fever in adjoining beds. They (*i.e.*, the Coombe Hospital) had one remarkable instance where they had a case of puerperal peritonitis, in which they thought it wise to apply leeches. This woman got erysipelas, and recovered, while the patients at each side died from puerperal fever, in one case, accompanied with effusion into the joints, and in the other, the patient died before that could have taken place." By a strange coincidence, Dr. Kidd's next sentence, and next branch of his subject, commences thus:—"The statistics of extern practice and of lying-in hospitals had been compared. If the results could be depended upon, lying-in hospitals ought to be closed at once and for ever. (Hear, hear.)" After expressing his want of reliance in the statistics furnished by extern maternities, he continues:—"But, notwithstanding all this, he must admit that there was a large proportion of mortality due to the influence of the hospital. He believed it was impossible to collect a number of patients under one roof, and yet not to have an hospital atmosphere, and that that atmosphere was more or less injurious." Here, Sir, we have the honest manly statement of this enlightened man—himself an hospital physician of no slight experience—conversant with his subject, and sustaining, to the letter, the views I have propounded, on the eve of building an hospital so constructed as to collect a number of patients under one roof, when he admits fairly, "it is impossible to collect them under one roof and not to have an hospital atmosphere, and that that hospital is more or less injurious." Is it to be wondered that I should, under these circumstances, implore him and his colleagues publicly, as I have already done in private, at least to hesitate in raising any structure that shall not render the isolation of parturients complete?

On the third night of our discussion, I made a few observations upon the papers that had been read that night; but, by some strange oversight, the reporter employed by the Society

to detail the proceedings omitted my observations upon the St. Petersburg Hospital in reply to Dr. Kidd. Dr. Kidd observed, in reference to isolating parturients, "When Dr. Kennedy spoke of isolating patients he meant it literally by having a separate ward for each patient. The plan had been tried in the hospital of St. Petersburg, which in 1852 had been reformed by the Grand Duchess Helena. It was increased by the erection of a new wing of the figure of the letter L on the corridor plan; opening off the corridor were a number of small wards in which the patients were placed. But what had been the result of that? The reform was instituted in 1852. The mortality for the seven years preceding it was 3·12, and for the seven years succeeding 2·93. That was to say, before the patients were placed in separate wards 1 out of 32·17 died, and that after this change—after they had undergone all this expense and trouble, and more or less injured the efficiency of the hospital, the only change was that 1 died in 34·09." Now, had the Doctor himself happened by any process of transformation to be one of the two lives saved, I doubt whether the *expense* and *trouble* would have stood in the way of his recommending the reform, inefficient as it was.

On this subject Dr. Mapother, no bad authority, writes to me, Dr. Kidd did not think the saving of 2 out of every 34 deaths worth the changes made in the St. Petersburg Hospital. Sanitarians are proud of reducing a death-rate by 1 in 1,000. But, my answer to Dr. Kidd on this statement, and which I complain of having been omitted, was based on the following extract taken from Dr. Oppert's volume on Hospitals and Infirmarys. In describing the Helena Hospital he writes thus—"The institution consists of an old part which was built more than thirty years ago, and a new one, the erection of which was patronized by the lady the name of whom the hospital bears at present."

"The whole has an irregular shape; the old part contains two floors, about fifty beds, the new one *three*, under one roof, not including cribs, can be placed in the wards. The old part has the shape of a letter L (reversed), and one portion contains a central corridor, into which small rooms open on each side, the other has one corridor running along the wards.

"In the new part, which has the form of an open quadrangle, the sick wards are small, for one or two inmates. Most of them contain open fire grates; there are tile stoves in some others. *The wards open into each other*, and are situated back to back on either side of the wall." And yet Dr. Kidd adduces this as an instance in which, as he himself expresses it, my plan of "isolating patients literally" was tried and failed. My answer simply is, that this is directly the *reverse* of my plan; that my plan has not been tested in the Helena Hospital, and consequently has not failed. Dr. Kidd might just as well have said, that the plan he and his confrères are about to carry out at the Coombe Hospital, of isolating or separating the patients *after* the attack of metria has shown itself, is my plan, and if it also fails, might hereafter affirm that in the Coombe my plan had been also tried and had failed. My plan recommended to certain parties in America who consulted me upwards of thirty years ago as to the best means of building to be adopted in the construction of lying-in hospitals, with a view to exclude metria, was that each building should be completely isolated, and with not more than two beds in each ward.

Dr. Mapother, in a few pertinent words, evinced how well he understood the subject of zymotic disease, upon which I may say, without flattery, he is "*facile princeps*," our highest authority in this kingdom. It affords me great satisfaction to know that I possess in this arduous struggle the support and unbiassed disinterested approval of this enlightened physician, who has made zymotic disease, its causes, prevalence, and laws, his special study, and whose writings and lectures have thrown so much light upon it. This liberal-minded physician, thoroughly versed in the use and value of statistics, has re-

corded his opinion, in the spirit of a jurymen or expert, and one who attended this debate with no determination to support a foregone conclusion—no mistaken idea that his darling hospital was attacked and must be defended at all hazards, provided with no elaborated one-sided brief that occupied weeks in the preparation, and hours in the delivery, but, best of all, with no motive but to arrive at truth. And what did this indubitably competent, this unquestionably honest expert and jurymen say? "He did not think one of the speakers had controverted the remarkable statistics which had been brought forward by Dr. Kennedy with regard to the mortality in the Dublin Lying-in Hospital, and that in small provincial towns, Waterford, Limerick and New Ross."

Sir, in dealing with the pertinent remarks of Dr. Churchill I feel bound to state that he has entered upon the consideration of the question at issue in a philosophic spirit, and that his observations have helped us much in the elucidation of this important subject. Nay more, I feel called upon to add, that however I may regret the insertion of the last paragraph of his paper, in which he pronounces "the changes I propose both *hasty* and *injudicious now*," yet the tenor of his reasoning, the negative-pregnant contained in the words not *now*, which mean, if anything, the necessity that shall or may exist hereafter, but above all, table of statistics, and the admirable rules he has so strongly insisted upon, in their reading and application, render his observations not only valuable, but of the greatest value, in confirming all the views I have propounded and insisted upon in my paper.

We shall pass over his strictures upon the statement attributed to me as to the non-occurrence of metria in patients in their own homes, by simply referring him to the words "*comparatively rarely*," which he republishes in my ninth proposition. The oversight in which he, in common with Dr. M'Clintock, giving Dr. Joseph Clarke's death-rate by puerperal fever, places it at 6 not 3, as it ought to be, out of his 3,847 private patients, a rate which so nearly coincides with mine, being 1 in 1,282, and the mistake which ascribes this statement to Dr. M. Clarke, whereas it was contained in a letter written by the late Dr. Joseph Clarke to Sir Charles Mansfield Clarke, that we shall again have occasion to refer to.

Dr. Churchill, sir, asks a very pregnant question, and one the answer to which contains exactly what we are looking for. If metria be produced *spontaneously*, why do long periods of freedom from it occur under precisely the same hospital conditions as those which accompany its appearance? This question is seriously asked me by my friend Dr. Churchill. Why, sir, the learned president of the College of Physicians might just as well have asked that unanswerable question that puzzled all the philosophers of the last century, and remains, as far as I am aware, still unanswered, "What is the weight of a mail coach?" I will ask him in return to substitute the adverb "*epidemicly*" for "*spontaneously*," and answer his own question, explaining why *epidemics* should recur under precisely the same circumstances, and it is not impossible, when he succeeds, he may apply the same solution to both questions.

Neither shall I dwell upon his views of the epidemic prevalence and contagious extension of metria views, so strongly confirmatory of what I have expressed. But I pass to his statistics. In the first instance, reiterating his own remark, "That to be of any authority they must be extensive," to which he added a more doubtful proposition, namely, "In fact their value is exactly in proportion to their extent." Had he substituted the words "comprehensiveness" and "accuracy" for the word "extent" I should have accepted the latter as freely as the former proposition. But possibly he intended to imply or include these ideas on the word "extent," and in that meaning, therefore, I shall deal with it.

Dr. Churchill treats of three classes of statistics, giving the proportion of death-rates in each. The first includes the mor-

tality of six obstetric practitioners, some giving the deaths by puerperal fever merely, the others the general mortality. Dr. Churchill justly remarks that they afford no sufficient ground for estimating the death-rate after confinement, and passes them without comment, a line in which I shall follow his example, merely remarking that, if we could hope by any exertion of ours to bring the death-rates in hospitals to any reasonable approximation to those detailed in his private practice tables, we should be but too happy.

The next class of statistics given by Dr. Churchill is that collecting the number of cases and proportion of deaths to deliveries occurring in the attendance upon out-door patients from the maternities—and here Dr. Churchill has his own principle of *extent* fairly carried out—he adduces no less than 236,665 cases as attended from six maternities, giving 1,590 deaths, or the proportion of 1 in 149 deaths by puerperal fever, and this he contrasts with 71,090 cases in large hospitals, giving 1,156 deaths, or 1 in 62—that is, he gives

Maternities death-rate, 1 in 149

Large hospital death-rate, 1 in 62.

Now, although I do not bind myself to the accuracy of these statistics, I accept them on the authority of Dr. Churchill as his basis of argument, and merely so far as they support his negative-pregnant that “*now* is not the time to provide small parochial hospitals,” and ask is it nothing to save 2½ to 1, on his own calculation, of all those women at present confined in the great lying-in hospitals? and if *now* it is not the time to do this, when will that time be, and what will be the additional unnecessary mortality that we shall then be answerable for when that time arrives? Simply repeating, that I am not answerable for any confusion Dr. Churchill may have fallen into in his attempt to give the mortality of puerperal fever distinct, as, finding myself the impossibility of doing this from the unreliability of the returns as well from some of the hospitals as maternities; in consequence of the irregular manner in which the different varieties of metria were reported, I adopted, as the only reliable test of comparison, the total mortality in all cases, unless when I state the contrary. I should much have preferred giving the mortality by puerperal fever in all cases, with the gross mortality, had this been available and reliable.

As Dr. Churchill has not drawn the distinction between deaths by metria and the total deaths, it would not be fair by him, nor would this discussion derive any benefit by continuing the comparison, or dwelling upon his returns of the large hospitals. We shall, therefore, pass at once to his third table, that of what he terms the small hospitals, and in doing this must be allowed to repeat Dr. Churchill's axiom—“In comparing numbers we must take care that we are comparing like with like.” Now, on this his own ground of comparison, I altogether reject this table of statistics, and deny that any ground of comparison holds. Dr. Churchill collects twelve *what he calls* “*small hospitals*” to make his comparisons by, and yet of these twelve *only three are* small hospitals, the other nine exhibiting all the vices of the larger lying-in hospitals, with none of their advantages. I feel convinced that this was an oversight on the part of my friend, or he never would have dreamt of drawing such a comparison as ranking these nine hospitals in the same category, or classing them as small or isolated cottage hospitals, such as I recommend. Nine out of twelve of these so-called small hospitals have annual deliveries varying from 400 to 140, and some of them contained as many as thirty and fifty beds. Several of them were old houses, with a number of rooms communicating, with story above story, and the patients huddled together, with every disadvantage of small crowded rooms, and a stagnating atmosphere. Why, compared to these the palatial edifices and well-ventilated spacious halls for dormitories, such as the hospital which is such a source of pride to us in our city, might even afford better chances to recovery to patients in their delivery.

Of the three cottage hospitals which I compared with the great hospitals, on the contrary, one had only 30 deliveries in the year, and the largest the Waterford had only 115, and these scattered over four rooms. Is it then to be wondered at, that in these three, the mortality only amounted to the average of 1 in 282; whereas deducting these three cottage hospitals from the twelve in which the mortality is given by Dr. Churchill as that of the small hospitals, I find the mortality of the remaining nine amounts to 1 in 59. Why I doubt whether a stronger case could be made for the cottage or isolated hospitals, than that furnished in this table of Dr. Churchill, or, if properly investigated, that any stronger proof could be given of the accuracy of my propositions, No. 3 and 4, which asserts the mortality to exist in proportion to the number of parturient patients cohabiting and breathing the same atmosphere, and that metria finds its habitat where large numbers are delivered under the same roof. Propositions that imply number in proportion to space, as well as absolute number; and yet, these proportions have been cavilled at by almost all my critics. Thanks to Dr. Churchill, however, he has answered these unanswerably in this table.

But, we have one more matter to touch upon with my friend Dr. Churchill. He very properly insists in statistical calculations upon the “numbers being very large, and the time embraced in them being considerable.” Very justly he remarks, “in a small hospital or private practice you may go on for years without a death, yet after the lapse of another year the average death-rate may be fearfully high, just because an epidemic intervened.” Now, I apply this rule to his table, and I find that the first and second entries, Dr. Beatty and Dr. Churchill's hospital statistics, only embrace three years, and are, compared with the Waterford Hospital, embracing thirty. It is hard to say whether, if the statistical kaleidoscope to which we alluded on our first night's discussion had revolved for the other twenty-seven years, Dr. Churchill and I might not have agreed upon this point, as we do on most others, and thus the convictions of his own well-stored mind, the result of years of ample experience and deep study, might have remained unchanged, and been applied in co-operating with me in this my arduous struggle for the benefit of our suffering fellow-creatures. Be this as it may, however, I would strongly urge upon him, when he is tempted to be led astray again by statistics, to hold fast by his own excellent maxim—“That in comparing numbers with numbers we must take care that we are comparing like with like.”

Dr. Morgan's report of the mortality in childbirth in the Lock Hospital, 1 in 74, is extremely interesting in its bearings upon this discussion.

It is quite evident that the paucity of the births and the consequent segregation of the parturient element was a main cause of the comparative absence of metria in his cases. But, on the other hand, we had the parturient exposed to what we laid down as a mischievous influence in her inhaling the atmosphere of a surgical hospital, an element that should have increased the mortality, as we have found it do, in the foreign hospitals in which surgical cases and deliveries are congregated, unless some corrective principle was in operation.

We imagine we have exactly met a principle in the theory, old as the fathers in medicine themselves, namely, that morbid poisons cannot coexist in the same individual. Here the syphilitic virus was in occupation and resisted the metria zymoticene.

This theory I am quite aware admits of some apparent exceptions, exhibiting modifications in the types of disease, depending upon intercurrent poisons; but here again the common original type may be the explanation.

I have, myself, witnessed strange struggles for the mastery in cases where two poisons had found a nidus in the same individual, at the same moment.

One of the most remarkable was a lady under my care about

two years since. Her children were ill with mumps, and she sickened with fever and stiff jaws, but without the glands assuming the usual enlargement. The fever, however, continued, and with considerable, in fact, unwonted severity, causing me some anxiety, and after four days, a crop of measles with all the usual accompaniments, appeared over the body, ran its course, and subsided on the fourth day; but the fever kept up. Difficulty of swallowing returned, the parotid and submaxillary glands became very much enlarged, and the case then ran the usual course of mumps.

Dr. Morgan's observation upon the distress of mind necessarily existing in the deplorable cases of labour in the Lock are of much value.

Whilst I freely admit the influence of mental depression in causing bad recoveries in childbirth, and even predisposing to puerperal fever, I am of opinion that its influence in the latter respect has been over-estimated in the observations that have fallen from several of the speakers upon this subject, but the very interesting report furnished by Mr. Morgan, of the Lock Hospital, and the South Dublin Union report, appear almost conclusive on this subject. What combination of conditions could be more calculated to produce mental depression than those of poverty, destitution, and syphilitic taint in the married female? but when we couple with these the frequency of seduction and prostitution as additional ingredients, we can scarcely conceive any influences more depressing to the human mind; yet, with this combination of depressing influences, the mortality in Dr. Morgan's cases in the Lock, with a delivery ward containing only *two beds*, and therefore never overcrowded, was only 1 in 74; whereas in the Lying-in Hospital, with its mixed occupants and incidental cases of seduction, it has been 1 in 31½. The only assignable cause of the excess being the proportion of the deliveries under the same roof, constituting the hospital the habitat of metria in the one case; whereas, every other ingredient of calculation, mental as well as bodily, was in favour of the excess in the other, but it was wanting in the habitat.

The South Dublin poorhouse furnishes us with a parallel nearly but not quite as strong as this.

(To be continued.)

Literature.

LECTURES ON CLINICAL MEDICINE.*

(SECOND NOTICE.)

THE next lecture is taken up with the important disease—scarlatina; nor do we know any work which embodies more valuable information on the subject than this one, for it may be called a work in itself. We would particularly notice the marked way in which he dwells on the great importance of having as accurate a knowledge as may be of the natural history of the affection. Also the comprehensive views he holds, and illustrates so well, of the cerebral and nervous phenomena, which, in the severer forms of the disease more particularly, are so apt to be developed. And, lastly, the varied complications of the affection both at its commencement and termination; complications which often render an attack fatal, which, *per se*, would not be so. Of these we may mention diphtheria, buboes, rheumatism, œdema of the glottis, &c. The only want in this lecture, as, indeed, in others also, is the treatment. We believe more may be done by treatment than what the author describes. His great reliance in severe cases, and particularly where the nervous symptoms predominate, is the cold effusion, for the use of which he gives special directions; with this he joins the preparations of ammonia and musk.

Now, we need scarcely observe, that in these countries, at least, many cases of the very worst forms of scarlatina occur, where the first remedy is out of the question. The patients

would not bear this heroic treatment. On the other hand, wine will in many cases be found of the greatest value, and this agent the author does not mention at all! With it, too, we may mention iron, especially the tincture of the perchloride, which seems to us to have a specific effect in those cases where the blood is profoundly altered, as shown by stripping and sloughing on the surface of the body. Anodynes too are, we know, of great service in many of these cases. It is now ascertained that the violent nervous symptoms so often present are not due to inflammatory action. Hence, anodynes are the more likely to be of use, and our own experience is entirely in their favour. This point of treatment is mentioned the more particularly, because it does not seem to have got the attention, even from English writers, to which it is entitled.

On the treatment of the anasarca of the disease, and the varied forms it may take, we are glad to be able to say that we entirely concur in that laid down by the author. It is judicious and to the point. We observe one measure advocated when convulsions occur—and in serous effusions these are by no means uncommon—and that is, compression of the carotids. We believe that this old plan, for it has been long since advocated, and put in force, is too much neglected, and that in suitable cases it might be adopted with advantage, that is, while other measures were being put in force. The author gives special directions for using this plan.

Our space prevents us noticing here some of the following lectures, such as those on measles, erythema odosum, urticaria, mumps, and herpes. One and all, however, will well repay perusal.

Dothemintaria is the subject of Lecture XV., and it, like the one on scarlatina, is most elaborate and practical. It is much more of an essay than a lecture, and occupies more than 100 pages. The author holds it to be a fever *sui generis*, and quite distinct from typhus. We have said that this lecture was elaborate, and this is shown by the numerous forms described, and also by the varied complications which may arise in its progress. Of the former he describes the mucous, biliary, inflammatory, adynamic, ataxic, spinal, cerebro-spinal, and malignant; while amongst the latter we notice different kinds of paralysis, sloughing of the cornea, dropsical effusions, œdema of the glottis, mortification of the extremities, &c., &c. It is worth noting that he gives cases where the gangrene attacked the upper extremities, after an attack of typhoid fever. This we guess, must be a very rare occurrence. We ourselves have seen different other parts affected with gangrene in the progress of fever, but not the anus. If the lecture on typhoid be elaborate, the one which follows on typhus is the very contrary, and it is quite clear that this is a type of fever with which the author was not at all familiar; and in proof of this it may be observed that the author's sketch of the affection is avowedly taken from Dr. Murchison's able work. It has indeed been long known that enteric is the prevailing fever of France; while typhus is very rarely met. We should have stated before that our author considers typhoid a very contagious disease, contrary to the opinion held by many in London.

The last lecture which we can notice here is on diphtheria; and if we have said anything already in favour of the author we must only repeat our praises more warmly now. For of all the lectures in the volume this one seems to us the most complete in its details. The disease has prevailed most extensively in France for at least half a century. Whereas, it is only within the last ten years it has prevailed in these countries, and in England much more than in Ireland. As far back as the year 1828, we find that the author was sent into the districts of France to report on the disease, which had then and there broken out, and from his accounts it might well be called a plague, for the mortality was fearful. Compared with it, cholera and scarlatina are mild diseases; even allowing their mortality to reach one half. It is to be noticed too, that though the disease prevailed in cities as Tours, where Bretonneau gained his experience of it, still it also was rife in villages, and some examples are given where as many as twenty died out of twenty-one attacked! In this lecture we would call attention to the varied ways in which diphtheria declares itself, when existing in an epidemic form. All kinds of wounds are liable to be affected by it. It attacks the surface of the body, as well as the mucous membranes; and any one would have a most erroneous idea who thought that it was a disease which only showed itself in the throat. In fact, the whole system is poisoned by it for the time being. Hence, even when the patient recovers, there are few diseases, if any, where the recovery is so very slow.

The different ways in which paralysis occurs after an attack

* Lectures on Clinical Medicine, by A. Trousseau. New Syd. Soc. Volume Second. Translated by John Rose Cromack, M.D.

of diphtheria are also well given by the author, and at great length. He states too, explicitly, that he was for a long time ignorant of the occurrence of this paralysis. This part of the lecture is illustrated by a number of well selected cases. He speaks likewise of the presence of albumen in the urine; but comes to the conclusion that no definite result arises from its presence. In other words it may or may not exist, and this does not seem to modify the severity of the attack.

Of croup, as a complication of diphtheria, the author speaks at great length. Nor is there, probably, any complication of more importance than this one, and the author's experience on the matter seems to have been immense. The treatment too is discussed in a way which leaves nothing to be desired.

Amongst other means, tracheotomy is particularly mentioned, and the author takes credit to himself, and we believe justly, for urging this measure, when others have failed. We may state that he operated in above 200 cases and of these one-fourth were saved! We must say this is a very large proportion of successful cases, and seems to us to prove the immense value of the plan. That it should be so successful, when we know the whole mass of the blood is so contaminated, is indeed a triumph of art. We need not say that the author dwells, in the most marked way, on the absolute necessity for operating early, and the choice of the case to operate on. The very fullest details are given for every step in the operation. In truth, the whole subject is treated by the hand of a master, and will well repay perusal.

The last lecture in the volume is on "thrush," and it, like the others, is most ably treated.

We cannot too strongly recommend this volume to the notice of our readers. It is literally full of practical matter of the greatest value, and its style is at once clear and lucid, and does not seem to have lost anything by the translation.

OZENA TREATED BY PERMANGANATE OF POTASH.

The *Marseille Medical* gives three cases of this troublesome affection, treated successfully by irrigations of permanganate of potash, the proportion being 5 parts to 100 of water, applied by means of an irrigating apparatus, furnished with a flexible tube, the patient's head being held forward, and a copious washing of the fluid used over the mucous surfaces. After the first few days of this treatment, the abominable odour speedily diminished, and a cure followed.

OPERATION FOR CRURAL HERNIA, FOLLOWED BY GANGRENE OF THE TRUNK.

A labourer, aged forty-two, who had a crural hernia for five years, required operation for its relief, which was performed on the 23rd April. No very unusual symptoms occurred till the 29th (six days after), but on the morning of that date, the patient complained of some pain at the right shoulder. On examination, sanguinolent vesicles had already formed, accompanied by a manifestly gangrenous smell; at 2 o'clock the entire right side was occupied by the gangrene, and at 5 o'clock he died.

On *post-mortem* examination, the intestinal tract was perfect, there being a little discolouration, at the site of the part that had been strangulated. No light was thrown on this unexpected termination, which appears unique.—*Gazette des Hôpitaux*.

BROMIDE OF POTASH IN DENTITION.

Dr. Salvatore Caro in an interesting paper read before the New York County Medical Society, on the use of this remedy in "summer complaints," remarks, in connexion with the disturbances arising from dentition: "In the most severe cases of odontitis either with or without ulcerated gums or loose bowels, I have never failed to relieve the child by the local application of the bromide of potassium. Almost immediately after the first rubbing, the gums, from being turgid, swollen, and red, assume their natural colour, and a certain amount of ease is felt. Saliva commences to dribble; and, as if by enchantment, agitation, carpopedal involuntary motion, vomiting and looseness of the bowels disappear. As the vomiting and diarrhoea in this case are not the consequence of gastro-enteritis, but an excitement of the stomach and the intestinal mucous membrane, owing to the inflamed condition of the gums, I suppose it will never be cured either by the scarification of the gums or by the use of astringents or anodynes; but, as I shall hereafter prove, simply by the use of the bromide of potassium."

REGISTERED FOR TRANSMISSION ABROAD.

WEDNESDAY, AUGUST 18, 1869.

RAILWAY INJURIES.

*DURING the late Assizes the papers have teemed with reports of actions brought against railway companies for alleged injuries sustained in accidents or through negligence on the part of the servants of such companies. In some cases very heavy damages have been given, and in others less, while in a case tried on Thursday the verdict was for the company. The number of the cases and other circumstances connected with them have given rise to many comments in the general press, and the differences of opinion amongst medical witnesses has added to the distrust with which professional evidence is too often regarded. It is deeply to be regretted that scientific witnesses should so frequently occasion by their conduct remarks detrimental to the profession, though, with our present mode of conducting such inquiries, it is difficult to say how such a result can be avoided. We are not about to transfer to our columns the accounts of all these trials, nor even to inflict on our readers an abstract of them. They are too much alike for this, and similar ones have too often been related.

We may, however, reversing the usual order of remark, call attention to the case in another column, copied from the *Times*, which conclusively proves that a railway company is liable to attempts being made to defraud it, and is consequently justified, in every case where a claim is made for compensation, in instituting searching inquiries. This right of inquiry is sometimes almost questioned, or, at any rate, its exercise is resented as an insult. It is, however, obvious that such a mode of regarding it is absurd; though the people who have been injured are apt, in this respect, to be very unreasonable. The same day (August 12) in which this impudent attempt at fraud was being tried on the Northern Circuit, civil actions were being heard on the Oxford and Home Circuits, in both of which the companies were successful in resisting claims. In the first, a man and his wife asked compensation for an accident

alleged to have occurred on the 23rd July, 1868. The patient was said to have suffered from renal calculus since 1862. No application was made to the company till this year, and they urged that after this time it was impossible for them to ascertain whether such an accident (a carriage getting off rails in shunting) took place on the day stated. In this case there can be no doubt that the defendants gained their verdict partly because the plaintiff for so long a period made no complaint, gave no notice, and by travelling about the patient might have aggravated her suffering from the renal calculus.

In the other case to which we have alluded, a passenger sued a company for damage sustained in falling or getting out of the carriage. Several passengers testified that plaintiff began to get out before the train had quite stopped, and the jury at once found a verdict for the company. This, again, shows how little consideration is shown by some people when a railway company is concerned. The still grosser case in which a jury gave damages for injury sustained through a fall by tripping in a hole in a waiting-room carpet, affords striking proof that companies are not likely to be unduly favoured by juries.

On the other hand, we should be the last to deny, as some seem almost disposed to do, that very serious injuries may be inflicted in railway accidents. A moment's consideration suffices to show that such terrible concussions as those that occur in collisions and other forms of railway accidents may produce very sad effects on the human frame. The worst of it is, that where the injury is very apparent it may not in reality be of such importance as where it is less obvious. Juries do not hesitate to give substantial damages for fractured limbs, as there is no possibility of deception. Yet it is natural they should feel greater difficulty in appraising injuries they cannot so readily understand. In the same way the loss of an eye by direct violence appeals at once to the strongest sympathy, while there would be a defence against alleged blindness produced by injury to the nervous system that could not so easily be demonstrated. It would to a certainty be urged that the blindness might have arisen from disease; and when professional witnesses differed, what could be expected from jurymen? Observations of this kind apply to almost all the disputed cases; and considering the uncertainty of our knowledge on many points that may be involved, we are inclined to think that juries have, on the whole, evinced an average degree of wisdom in their decisions. We are consequently not prepared to supersede them by any other mode of trial; nor are we at all sure that a system of obtaining skilled evidence could be devised which would in practice work with any great degree of accuracy and justice.

We have known men attempt to make a profit out of a railway accident—we have known them successful in their efforts. But we may trust that those capable of unjust extortion, even from a company, are the minority. On the other hand, no one will deny that companies have not unfrequently been guilty of much provocation by the annoyances and delays they have interposed. When they are clearly liable, it would be much more to their own interest to meet the cases promptly and even generously. And this is especially true in the cases of the poorer sufferers. A man of property may not be inconvenienced by the law's delay or expense, whereas one dependant on his earnings fears to put legal machinery in operation, however assured he may be of his rights. This is why some

few fall into the hands of pettifogging lawyers, who work with a single eye to costs. This evil would be remedied by prompt and fair dealing on the part of the companies; and we certainly hope that they will take this point into consideration.

Notes on Current Topics.

The Medical Council.

LAST week we remarked on the unanimity that prevailed in the medical and general press on the needful reform of the Council, and on the fact that the Leeds meeting had pronounced for the measure we have advocated, and that was so forcibly supported by Dr. Haughton. We have now to announce that the *Lancet* has wheeled round, and in its leader of last Saturday completely contradicts its prior articles. The tergiversation of this journal is proverbial, and need excite no surprise; but such contradictions are apt to make people ask whence they arise. The article to which our attention has been directed supplies no motive for the change, unless the following paragraph be deemed one:—"Under the skilful management of Professor Haughton, the meeting was made to behave like the Irish rebels in 1789." Is the hatred of the *Lancet* towards everything Irish so intense that it cannot bear to hear an Irishman advocate the views it has itself endorsed? Such petty jealousy will bring its own reward. A paper so excessively weak as our contemporary has lately become must be permitted the effeminate privilege of changing its mind under an inducement too slight for others to care for. The Profession in Ireland is not likely to trouble itself about the prejudices of the *Lancet*, nor are such men as Professor Haughton likely to care what that journal says.

The Introductorics.

THERE is to be no Introductory Lecture at St. Bartholomew's at the opening of the ensuing Session. At the London Hospital, Dr. Meymott Tidy will deliver the usual Opening Address; at University College, Sir H. Thompson; at King's, Dr. Johnson; at Guy's, Dr. H. Fagge; at Middlesex, Dr. Liveing; at St. Mary's, Dr. Cheadle; at St. Thomas's, Dr. Stone; at Charing Cross, Dr. Silver; at St. George's, Dr. Wadham.

Army Report.

THE new Army Blue Book has been issued, and is, as usual, of formidable size, containing a vast amount of valuable information, comprising a series of statistics, reports, papers, and cases, such as we have noticed in preceding volumes; and we have little doubt that the present will favourably compare with its predecessors. We propose on a future occasion to devote some space to an analysis of its contents.

Leaf Evaporation.

M. DEHERAIN has communicated to the Paris Academy the results of his investigations on the conditions of evaporation from leaves. He shows that it is governed by totally different conditions from those which determine the evaporation of inert liquids, for it continues in an atmosphere saturated with water, and is specially influenced by light.

The Lunacy Report:

THE Twenty-third Report of the Commissioners in Lunacy, ordered by the House of Commons to be printed, is now ready. It shows that the number of lunatics in asylums is considerably increased; but this result, as we have before remarked, by no means proves that lunacy is a more prevalent disease than formerly. It shows only that we take more care of our lunatics, and, perhaps, also that we pay more attention to its diagnosis and treatment.

New Act on Greenwich Hospital.

By an Act just printed the benefits of the Hospital can now be extended to invalids, although not in the receipt of naval pensions, who, before or after the Act, were invalidated for disease or wounds contracted or received in or by the service of the Crown, "or are infirm and helpless." Greenwich Hospital or a portion may be used for public purposes.

Native Indian Surgeons.

THE *Central India Times* publishes particulars of the death of Mr. Barrett, of the Revenue Survey at Chanda, who died from the effects of wounds received from a tiger. The wounds were by no means serious, and would have yielded to ordinary treatment. Instead, however, of applying the usual simple remedies, his stupid servants poured hot *ghee* over the wounds, and applied other equally absurd native remedies. As was to be expected, the arm rapidly became worse, and the camp native doctor was sent for. This unworthy, to complete what the others had begun, enjoined that the arm should be kept in a perpendicular position, to ensure which the arm was tied up to a point over the patient's head. The consequence was, mortification set in, and though the unfortunate gentleman was at once removed to Chanda for treatment, all the skill of the medical officer there proved of no avail, so rapidly had the mortification advanced, entering the shoulder and eroding the subclavian artery, the hemorrhage from which (chiefly internal) caused immediate death.

After the Dust-Bin.

As an Appendix to his Report on the Sanitary State of Paddington, the medical officer of health (Dr. Hardwicke) gives an account of some offensive trades carried on on the wharves of the canal basin. This enquiry was undertaken on the request of the Public Health Committee; and we may add that in reference to such trades Dr. Hardwicke makes some very valuable suggestions as to the conditions that ought to be imposed on those who carry them on. Our immediate object is, however, to enlighten the reader as to what really becomes of the contents of that domestic nuisance—the dust-bin.

This is what Dr. Hardwicke tells us:—

"The next kind of trade to be noticed and carried on largely on the Paddington Canal Basin consists of contract jobs for the collection and removal of household dust, cinders, ashes, and trade refuse, including in it offensive garbage of various kinds, mostly fish bones and animal putrifying refuse finding their way into the dust-bin. Several parishes, or parts of parishes, bring their dust through and into this parish for sifting, or as it is termed manufacturing, and removal. At the present time (November, 1868)—

St. Pancras (5 wards)	sends	40	loads	daily.
St. James	"	18	"	"
Marylebone (5 wards)	"	42	"	"
St. George, Hanover Sq.	"	18	"	"
St. Giles, Bloomsbury	"	26	"	"
St. George, Bloomsbury	"	20	"	"
Paddington	"	30	"	"
Kensington	"	40	"	"
		234		

The dust-sifting operations consist in the separation of dust refuse into four different parts. It is at present carried on chiefly by women in the open air. Of the four ultimate products, one of most value is called the "breeze," consisting of cinders and small coal—this is sold to brickmakers and used for brick-burning. This "breeze" has hitherto been allowed to accumulate on the wharves in large heaps; and although as a rule there is nothing offensive in this material,—yet in the summer months a small amount of vegetable matter (principally pea-shells, difficult to separate) renders it liable to become heated and undergo slight decomposition and putrefaction. It therefore contaminates the air for a considerable distance around, while it becomes so heated.

The next product, called "hard core," consists of pots and pans, stone jars and bottles, clinkers and broken crockery, old boots, &c., it is put aside for the foundation of roads. It often comprises oyster and fish shells in an offensive condition.

The "soft core" is the next product; it contains sufficient wood, old straw, paper, mattings, &c. to make fuel for heating a furnace. The destruction of "soft core" by burning has been a very recent experiment, and is intended to save the large weekly cost of removal by boat. This soft core contains large quantities of decaying vegetable matter, and other offensive things, and animal filth in the form of dead cats, dogs, rats, rabbits, &c. may be found occasionally. The smell from the chimney is complained of in the neighbourhood. Complaints and petitions have been presented recently.

The fourth product represents the ashes or small siftings, consisting of nearly half of the gross bulk collected. After being sifted it is placed in boats and taken off into brick-fields or by trucks from Great Western Railway to brickmakers, and is mixed up with the clay and burned with the substance of brick.

"Quiet and Private," of Course.

From an advertising column of a morning contemporary we clip the following rather suggestive *morceaux*, and reproduce them (omitting for obvious reasons names and residences), grouped and displayed in the obtrusive boldness and unblushing impertinence of the originals. If the moral state of this vast metropolis be so very much below zero as these advertisements justify the casual reader of them to believe, surely the catchpenny serpent-lairs, maintained by such a lamentable state of things—notwithstanding their "quietude" and their "privacy"—should be immediately placed under, if not entire supervision, close and stringent inspection.

FURNISHED APARTMENTS for a lady, with every care and attention (superior and private), eight miles from town.

FURNISHED APARTMENTS for a lady (quiet and private) in the house of a nurse, with care and attention. Terms from 10s. per week.

FURNISHED APARTMENTS for a lady (quiet and private), in the house of an experienced nurse. Every care and attention.

FURNISHED APARTMENTS for a lady (private), in the house of an experienced nurse. Good home. Large garden. Established twenty-three years.

Medicine and Surgery in Japan.

A BLUE book has appeared relating the journeys of four British Consuls in China and Japan. One of these

will be interesting to our readers as it gives an account of an expedition in Japan, undertaken by Dr. Willis, the chief object of which was to offer European professional aid to the sick and wounded in a local war then on foot between the Mikado and the Aidzu clan. The doctor's services were accepted by the Prince commanding-in-chief, a young man aged 24, and the Japanese Minister for Foreign Affairs afterwards forwarded to the Consul, on behalf of the Mikado, a letter of thanks and a present of seven rolls of brocade.

"Only at one place in all his journey was Dr. Willis molested. At a mountain pass some guards belonging to a local Daimio ordered him to take off his hat, and attempted to force him into making obeisances; the Consul resisted, and refused to proceed until apologies had been tendered. Two high officials were sent to look into the matter, and the chief of the guard, being ordered to make a formal apology, not only did this with a good grace in front of the guard-house, but offered, with the greatest readiness, to put an end to himself should it be thought that in the zealous discharge of his duty he had overstepped the limits of propriety. On his way to the seat of war in Echigo, Dr. Willis had ample opportunity of observing the country and people. There is no doubt that foreign trade is already extensively benefiting Japan: European money has given a great impetus to cultivation and manufacture, the staple of silk has doubled in amount and its price risen sixfold during the last ten years; the hill-sides are being gradually covered with mulberry plantations, and Dr. Willis thinks this production is capable of indefinite extension. In the silk districts the condition of the people is already much improved. The Consul notices that in one of these six coolies carried his litter running, while in the Aidzu country, which is turbulent and poor, sixteen of them had not strength to go beyond a walk. All through the island foreign cotton and woollen goods were met with, and the traveller was everywhere told that the demand for them was steadily on the increase.

"Dr. Willis arrived at the seat of war soon after the taking of the castle of Aidzu, the rebel Daimio. He observed a significant absence of wounded prisoners, and represented to the Commander-in-Chief the compassion always shown to them in other countries. But he was met by the excuse that the Aidzu prisoners reviled and insulted the Mikado's authority so offensively that it was impossible to spare their lives, and on another occasion the young general replied evasively, 'We have well considered the matter.' But every effort was made to protect the Consul from hardship and privation, and for his attentions to the Imperial troops and to such rebel wounded as were left he was repeatedly thanked. He bears testimony to the bravery and hardihood of the Mikado's army; he himself was in comfort and luxury compared with the fighting men, and yet the severity of the cold, joined to the poverty of the food, was so trying that his servants and assistants nearly all broke down. After a long day's work the only refuge was a shed open to the weather, and the only meal rations of rice and stale fish, eating huddling over the warmth of a charcoal brazier. Dr. Willis's conduct was most meritorious; without remuneration he remained with the army until he had done all that was possible for the sick and wounded, rebels as well as Royalists. It was very hard to persuade the Mikado's officers that the former should be treated as well as their own men; but at last Dr. Willis succeeded in obtaining supplies and quarters for them, performing himself all the necessary amputations, &c., and after instructing the native doctors as far as circumstances would permit, he returned to Yeddo in time to enter on his consular duties on the first day of this year, when it was opened to Europeans as a port of trade."

The Health of Mr. Gladstone.

THE Premier's late illness arose from an attack of mucous

diarrhoea, which was severe, and threatened at one time to become obstinate. On the 2nd the disease appeared to be wholly subdued; and Dr. Andrew Clark, under whose professional care the Premier had placed himself, reluctantly assented to his resumption of full official work. On the 6th there was a slight relapse, which was completely overcome by the 8th. On the 10th Mr. Gladstone left for a visit to Walmer Castle, where we trust he will quickly recover all his accustomed health and strength.

A Rational Statement on Water-Supply.

So much prejudice has been expended on the water supply that we are not sorry to have to report a rational statement which we find in the Sanitary Report on the Health of Paddington. The medical officer of that parish issues the following remarks in his annual report:—

"The Thames overflowed its banks in October and in January, and by washing the cultivated fields and receiving the contents of suddenly flushed sewers of Oxford, Windsor, and Reading, had become contaminated with an unusually large proportion of organic impurity. In a letter from Mr. Coe, the Secretary of the Grand Junction Water Company—in reply to a desire expressed by the Public Health Committee to learn if the Directors have under their consideration any measures that could be suggested to remedy the pollution of the water, it appears that in 1866, five Thames Water Companies lent their assistance to the passing of an Act for the re-modelling of the Thames Conservancy Board, and for the adoption of stringent measures to prevent the flowing into the river of the sewage of towns and other noxious matters, and the Companies voluntarily bound themselves to contribute the sum of £1,000 per annum each to the Conservancy Commissioners for the purpose of carrying these objects into effect. The Act of 1866 extended to the tributaries of the Thames for three miles in a direct line beyond the point of junction, and was supplemented by a further Act in 1867.

"The extreme limit of time allowed for accomplishing the total interception of all town drainage, &c. was three years from the passing of the Act, which period will terminate in the early autumn of the present year. The Water Supply Committee of the House of Commons of 1867 recommends further, that some representatives of the Thames Water Companies should be added to the Conservancy of the River to protect the Water Supply of the Metropolis. This recommendation has not, however, yet received the sanction of an Act of Parliament. After this assurance that every care will be taken to guarantee for the future a pure supply, all fears on the subject may be allayed. I may mention that besides the precaution just alluded to, a Report of Lieut.-Colonel Ewart to the Home Secretary recommends additional means for guarding against river pollution in places that may be adapted for town drainage. There is no doubt that the oxidising power of vegetation in streams and rivers of large size, running distance of 10 or 12 miles, is in itself often sufficient to remove all noxious quality of sewage water poured into them. There are differences of opinion on this point, but abundant evidence goes to show that the Metropolitan Public generally, and the inhabitants of Paddington especially may rest satisfied that the Thames really will in future furnish an abundant and pure supply of water at a moderate cost. But the system of storage in cisterns, placed so near the water-closet or the dust-bin, that the water becomes readily defiled by the gaseous emanations therefrom, ought to be abolished. A petition should sooner or later be prepared by the Vestry for the adoption of the 'constant supply system' as used at Manchester and other large towns."

Injection of Ammonia into the Veins in Snake Bite.

THE *Launceston Examiner*, of the 25th March, contains particulars of the case of James Brown, residing at Whirlpool reach, Tasmania, who was bitten in the arm by a snake on the 2nd of that month. This man, treated in the

first instance with the old remedies, was subsequently brought to the Launceston Hospital, where ammonia was injected into a vein in his leg. On the following day he returned home apparently cured. A few days afterwards, however, unfavourable symptoms set in, the leg became black in the vicinity of the injection, the discolouration extended downwards to the toes and upwards to the neck, leaving a well-defined line of separation from the other parts of the body. The discoloured side was, moreover, characterized by immobility and loss of sensation, almost as complete as if they resulted from paralysis. Happily these formidable symptoms began to subside, the blackness gradually disappearing, though it still continued in the vicinity where the ammonia had been introduced.

Penalty for Infringement of the Vaccination Act.

ARCHIBALD J. MILLER, a chemist and druggist, was summoned last week, by the prosecuting officer of the Poplar Union, for having signed a false medical certificate contrary to the provisions of the Vaccination Act. A summons had been served upon a Mr. Monk, the father of a child in the parish, for not having had the child vaccinated, and the mother went to the defendant's shop, and asked him what she was to do, as the child was not in a fit state of health to be vaccinated. The defendant took the certificate into his parlour, and afterwards brought it out signed by himself, with the name of Dr. Powles.

The defendant said Dr. Powles was in his parlour, drawing a tooth for a lady, and he asked him to sign the certificate, but being very much occupied, he told defendant to sign it himself, which he did in Dr. Powles' name.

Dr. Powles said he had no recollection of the circumstance, but he was too busy to attend to what was asked at the time. However, if he had been requested to sign a certificate that the child was unfit for vaccination, he would have done so, as it was certainly the truth.

Mr. Paget committed the defendant for trial.

Poisoned by Laburnum Seed.

ON Sunday week a serious case of poisoning by eating the seed of the laburnum occurred in Carlisle. In the afternoon a number of boys belonging to Caldewgate went out into the country, and while strolling along the road filled their pockets with laburnum pods. On their return to Carlisle they gave some of the poisonous seeds to their playmates, and about an hour afterwards about a dozen of the children who had partaken of them became seriously ill, and vomited freely. The parents of the children, becoming alarmed, sent for Dr. Hair, of Abbey-street, who applied such remedies as he thought necessary, and under his treatment the children (the lives of several of whom were in serious danger) recovered. This is not a solitary instance of similar effects from laburnum seed.

Cholera in Poona.

WE regret to hear that cholera is on the increase in the city of Poona. The approach of rain will, we hope, mend matters.

Autumn Complaints.

THE dulness of the season opens the columns of the daily papers to all sorts of complaints that at other times

cannot be attended to. Already letters have been admitted into the newspapers which, had Parliament still been sitting, must have been written in vain. Medical men have also obtained a hearing. One has related in the *Times* his misery on account of the want of punctuality in suburban trains. Another has raised his voice against the everlasting noise which renders night hideous in almost every London street, and which is worse for patients than for over-worked doctors. Both grievances could easily be remedied, and we are glad that the *Times* has allowed a corner in season to these subjects.

Sir J. Gray, M.P., and Medical Reform.

SIR JOHN GRAY, M.P., has given notice that next year he will introduce a Bill on medical education. A contemporary hopes he will take no step without consulting the corporations. Why, this would be to ask them how to remedy the consequences of their own neglect of duty. The journal threatens that the corporations will unite to oppose him unless they are consulted. So much the worse for the corporations, and so much the better for the Profession and the public. Let them thus publicly exhibit themselves as pure obstructives and their day will be over. We trust Sir John Gray will ignore all the corporations, and set at nought their so-called vested interests. It is time the vested interests of the public were impartially considered.

Coroner's Work.

DR. LANKESTER'S Annual Report as Coroner for Central Middlesex has been issued, and contains a number of interesting facts and suggestions, upon which free discussion took place at the meeting of the Health Department of the Social Science Association, where the Report was first read.

Dr. Lankester remarks that the recent movement for the improvement of the workhouses originated through disclosures made in the Coroner's court, and he would seem to be of opinion that an inquest might be held in every case of death in workhouses. In the case of persons found dead there should always be an inquest; and Dr. Lankester remarks that this rule is needful even where persons have long been ill, but are unexpectedly found dead.

So in sudden death occurring to persons known to suffer from a disease likely to terminate thus, he remarks that these are just "those lives that would be most exposed to the tampering of those who were interested."

The question of the registration of "still-born children" is entered into at great length, and there are other points in the Report deserving careful attention.

Outbreak of Cattle Disease in Surrey.

DURING the last few days a contagious disease among cattle broke out in Surrey, and is most prevalent among milch cows. The epidemic is known as "the foot and mouth disease," and is the same type of disease which prevailed previous to the great outbreak of rinderpest. At Brixton, Clapham, and Camberwell it is raging to a frightful extent, and the whole of the sheds of cows are affected, and in some instances herds of from fifteen to thirty milch cows are down with it. That it is contagious is without dispute, although it is not of a very fatal character. The

animals are seized with soreness in the feet and tongue simultaneously, and are unable to stand or take food for ten or fourteen days; they lose their milk, waste flesh, and dairymen are driven to great extremities to obtain milk for their customers. It is generally thought that the disease has been imported into this district by foreign cattle, and it is rapidly spreading over other localities in the county.

Public Mortuary for the East of London.

THE Poplar District Board of Works have decided upon erecting a public mortuary upon a plot of land which they have purchased from the Tower Hamlets Cemetery Company. When completed the mortuary will be for the use of the three parishes over which the Board has jurisdiction.

At the last meeting of the vestry of St. George the Martyr, Southwark, attention was called to the manner in which fever and small-pox are generated, the first by the over-crowding of the poor in narrow lanes and alleys, and the second through the refusal, as well as the neglect, of the same class to carry out the Vaccination Act. It was stated that an order had been obtained to remove from a house in Harrow street a dead body which had been kept amongst the living more than twelve days.

MR. BAKER, of Kew, has been appointed to the Chair of Botany at the London Hospital. Mr. J. F. West takes that of Anatomy at Queen's College, Birmingham.

THE decimal system has been adopted by the Editors of the new Austrian Pharmacopœia. The gramme and its multiples are to replace the ounce and the grain, and a Commission is already named to fix prices in accordance with the change.

IN his return for last week the Registrar-General states that the deaths of eight persons who were killed by horses or carriages in the streets of London were recorded. This is at the rate of more than 400 a year, while the fatal accidents on the railways of the United Kingdom average rather over 200 a year. In the seven days to which this return relates, the mortality from street accidents in London was twice as high as that from small-pox and intemperance combined.

THE session at the Army Medical School at Netley terminated on Monday week. The officers who received commissions in Her Majesty's Indian Medical Service obtained leave of absence until the day fixed for their embarkation. The Herbert Scholarship was awarded to Dr. Christopher W. Calthrop, late of Charing-Cross Hospital. The prize presented by Surgeon-Major Fleming (late 4th Dragoon Guards) for the best examination in military surgery was obtained by Assistant-Surgeon Joseph J. Pope, Royal Artillery.

THE Glasgow death-rate for the last quarter has been just 50 per cent. higher than in London and thirteen other large towns in the Kingdom. In these fourteen towns the death-rate for the last quarter was 24 in every 1,000. In Glasgow it was more than 36 in every 1,000, while in the

corresponding quarter of 1868 it was only about 30 in every 1,000. The Registrar-General dwells especially upon the fact, and assigns very intelligible causes for it. Though the water at Glasgow is good and abundant, the dwellings of the poor are execrable. Nothing can be worse in the way of crowding, want of space, want of ventilation, want of decency, and want of everything which tends to lift the poor, and especially their children, from the lowest depths of degraded pauperism. Even in Liverpool, still bad enough, but where the infamous cellar system is to a considerable extent abolished, the deaths in the last quarter were only 27 in each 1,000. In Bristol, of old notorious, they fell from 23 to 21 per 1,000. And in Birmingham they fell from 20 to 18 per 1,000.

DR. ROBERT ALDREN, of the Madras Army, we learn from the *Madras Mail*, fell a victim, the week before last, to jungle fever, while employed on the Upper Godavery works, which have caused so large an expenditure of human life. He entered the medical service so recently as April 1867.

IT is announced from Nusseerabad, that a fresh outbreak of cholera has taken place there of a fatal type. Up to the afternoon of the 30th ult. there had been twelve cases in the Royals, with ten deaths. The Artillery remained free from the scourge, and the N. I. had suffered comparatively little. The natives were suffering much. In the district of Azingurh, also, the disease is prevailing. Medicines had been deposited at each police station for distribution to all applicants.

AT a meeting of Liverpool medical men last week, it was agreed that the committees of the various sick benefit societies in the town should be requested to increase the rate of remuneration for the medical officers from 3s. to 4s. per annum for each member.

SCOTLAND.

LIGATURE OF THE AORTA IN EDINBURGH.

ON Friday, the 6th inst., Dr. Patrick Heron Watson tied the aorta on account of secondary hæmorrhage from the common iliac artery after ligature. The iliac had been tied nine weeks before with catgut, under the most careful antiseptic precautions, and employing similar after treatment. In spite of this, internal hæmorrhage set in, distending the iliac fossa and cavity of the pelvis, and escaping partially by the yet unhealed incision.

The artery at the point of ligature was found to be completely divided, but no trace of the catgut ligature was discovered. The diseased condition of the arterial tunics precluded the application of a ligature to the stump of the iliac. Dr. Watson, therefore, plugged the vessel with his forefinger, took off the Dubois' aortic tourniquet, made an incision in the linea alba, opened the cavity of the abdomen, turned aside the bowels, cut through the mesentery, cleared the aorta half an inch above the bifurcation, and, carrying a ligature round it with a common aneurism needle, secured the vessel with a common silk ligature. He also secured the external and internal iliac branches upon the affected side, so as to prevent recurrent bleeding.

The patient went on well for the first forty-eight hours, but after the sixtieth hour gradually sank, dying sixty-five hours after the operation—living, however, longer than any of the eight recorded cases, except the one of Monteiro, in which the patient survived the operation ten days.

The operation was undertaken merely to prevent inevitable death from hæmorrhage, which must have proved instantly fatal unless the ligature of the aorta had been performed. No further bleeding took place. The limbs regained their temperature after the operation, but before death the left limb (the side on which the iliac had been tied) had sunk in temperature some six degrees below the other, as high, at least, as the knee; above this the temperature was the same on both sides.*

ADDRESS TO DR. SANDERS.

THE following address, signed by nearly 300 students, has been presented to Dr. W. R. Sanders:—

“To William Rutherford Sanders, Esq., M.D., &c.

“SIR,—We, the undersigned Students of Medicine, having heard that you are likely to be a candidate for the vacant Chair of General Pathology in the University, in the event of its being rendered vacant by the resignation of Professor Henderson, embrace this opportunity of expressing our high sense of your qualifications for that position. You have for many years enjoyed a well-earned reputation in this School as a Lecturer on Physiology, Pathology, and Clinical Medicine, as a practical instructor in histological anatomy at Surgeons' Hall, and as a zealous clinical observer and teacher in the Royal Infirmary. The fact of your having held, for upwards of fifteen years, the post of Conservator of the Museum of the Royal College of Surgeons, which contains a collection of pathological specimens scarcely equalled, shows the high esteem in which you are held as a pathologist by the members of our profession, and is itself a special qualification as a teacher of morbid anatomy. Your many and original contributions to the literature of medicine, more especially your recondite researches into the pathology of the nervous system, and the healthy and morbid functions and anatomy of the spleen, have given you a very high place amongst the promoters of scientific medicine; while the efficient manner in which the *Edinburgh Medical Journal* has been conducted since it fell into your hands, sufficiently testifies to your literary capacity and to the extent of your medical erudition.

“Those of us who have come into actual contact with you cannot refrain from expressing their appreciation of your great forbearance and uniform kindness to your pupils, and the readiness that you have ever displayed to encourage inquiry, as well as the lucid manner in which you have explained all points of difficulty, and the accuracy that has invariably distinguished your statements. We also bear witness to the pleasure with which we have listened to your lectures, and to the instruction they have conveyed; to the painstaking, laborious, and philosophic investigations on which they were based; and to the clear and concise and careful manner of their delivery.

“In conclusion, we most sincerely hope that your candidature may be successful; feeling, as we do, that your appointment would sustain the efficiency of the chair, and add to the lustre of our University.

“Edinburgh, July, 1869.”

GLASGOW INFIRMARY.

DR. M'CALL ANDERSON succeeds Dr. Leishman as Physician. In him the Infirmary will find an able physician, and the pupils a clinical teacher of great skill. Dr. George Buchanan succeeds to the surgery vacant by the term of office of Professor Lister during.

ABERDEEN.

THE capping of Graduates was held at Marischal College, under the Presidency of Vice-Chancellor Principal Campbell.

* Sir A. Cooper first performed this operation in 1817. Since that date it has been done twice by Mr. James, of Exeter, and once by each of the following Surgeons—Murray, at the Cape; Monteiro, at Rio; South, in London; Hunter McGuire, of Richmond; and Watson, Edinburgh.

Transactions of Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

WE have already given a general account of the proceedings of this useful society at the annual meeting, at York. On an income of little more than £250 the society carries on its proceedings, and supports its journal. We very much question whether it can expect to do as much at the same cost should it amalgamate with the proposed new Royal Society of Medicine. The new President (Professor Laycock) took as the subject of his address the “objects and organization of the Medico-Psychological Association,” so that in furnishing our readers with an abstract of the annual address, we shall at once give the most authoritative information about the Society and afford some idea of one of the ablest addresses delivered on similar occasions.

Having returned thanks for the honour conferred upon him in electing him President, Professor Laycock said:—

According to the second rule of its establishment, “the improvement of asylums and hospitals for the insane; the acquisition and diffusion of a more extended knowledge of insanity and its treatment; and the promotion of a free communication on these subjects between the members,” the association was restricted, if that rule were literally interpreted, to the pathology and treatment of insanity and the management of the insane in asylums and hospitals. The cultivation of both mental science and medical psychology was eminently one of the objects of the society. If the history of the chartered medical colleges and the various medical societies, and indeed of all professional associations whatever, were examined, it would be found that their objects were threefold, viz., the maintenance of the secular or social interests of the members, such as are comprised in social position, legal relations, and adequate remuneration; the interchange of professional experience; and the advancement of the department of art and science practised and cultivated. The Psychological Association was first constituted for the attainment of the two first classes of objects by medical officers of asylums exclusively; to these the third has been added lately, and the membership extended. Matters of daily duty were obviously of primary importance, so that information as to all that concerns asylum management and treatment of the insane must be always useful and interesting to the majority of the members. Would not a standing committee charged with the duty of collecting and reducing this information to order, for a special department of the journal, be advisable? Another committee might take charge of the defence of their social position and interests. The establishment of such a committee had been advocated, and its duties sketched out by Dr. Conolly in September, 1862, when, doubtless, he had in his mind the serious fact that only a few months previously a peer of the realm, high in office at the time, and when exercising the duties of his office, as the legal guardian of the insane in his place in Parliament, declared that to consider insanity to be a physical disease, which they all did, was “an evil habit” which ought to be corrected, and who contemptuously designated physicians like Dr. Conolly, “mad doctors.” It was not surprising that such a high and public example should be followed elsewhere, with the injurious results Dr. Conolly lamented. Dr. Sankey, also, in his address of last year, dwelt forcibly upon the isolated and defenceless position of the association, and his predecessor, Dr. Robertson, reported his active efforts in regard to a Bill which seriously affected the pecuniary interests of many members, and which were again involved in the County Administration Bill. The duties of a defence committee would chiefly bear upon injurious opinions and proceedings as manifested in the press, in Parliament, and in the courts, and such a committee would have a wide scope for action in the diffusion of information. Much of the misapprehension to which Dr. Conolly referred had its origin in deeply-rooted prejudices. Many persons had as great a fear and dread of the insane as they had of wild beasts or of dangerous criminals, and they looked upon asylums as places of detention, and on the medical superintendents as little better than jailors. The horrible treatment of the insane formerly practised in places of detention, in accordance with these sentiments, was not yet forgotten, and supplied incidents for sensational novels. The defence committee would seize every available opportunity to combat these hurtful and barbarous sentiments. They could clearly show that the insane are unjustly and wickedly treated when treated as the outcasts of

society; that they have a claim on it to solace and sympathy; and that, influenced by these moral truths, the calumniated "mad doctors" have been the chief agents in effecting all the great modern improvements in the treatment of the insane, in the face of the most profound ignorance and the most obstinate prejudices. A defence committee would not be content, however, merely to combat these prejudices. Psychological science was, he said, rich in substantial benefits to society itself, if rightly applied. In aiming at the prevention and cure of insanity, higher and more important objects were attained than were comprised in the effective management of asylums. Statistics carefully drawn up by his friend, Dr. Thurnam, showed that of the insane brought under treatment in asylum within three months of the commencement of the disorder, eighty per cent., or four-fifths, were restored to health, even when the most hopeless cases were included in the calculation, but, if those complicated with fatal diseases like consumption and apoplexy were excluded, then nine-tenths were curable. If, however, that treatment were delayed from three to twelve months, not one-half were curable. It was obvious from these facts that early treatment was the greatest economy, but few thought of the sad consequences which ensued when the disease was left to run its course, in the almost complete dissolution of family ties and the abolition of domestic affections. In too many instances the hopelessly insane were wholly neglected by their relatives, so that their physician takes the place of a father and brother. These facts showed how criminal, as well as foolish, was the conduct of those who hindered early treatment by describing mental medicine and the practice of it in hospitals and asylums for the insane as a horrible thing, to be avoided at all hazards. Professor Laycock said he need not dwell upon the dangers to society and families thus caused, upon the hindrances thus raised to the successful practice of medico-psychological art and the proper recognition and remuneration of their arduous duties, but would urge that a committee in protecting their social and secular duties would be effectually serving the interests of humanity and of society. Mental physicians had, he said, frequently to advise families and courts of law in cases of vice and crime, in which mental disorders and defects were pleaded in extenuation of consequences, and, in the exercise of those duties, had to encounter prejudices of another kind. It was useless to conceal the fact that they were thus chiefly involved in a conflict of new ideas with those old notions which formerly led and still lead directly to the cruel treatment of the insane. When Cullen, one of the most distinguished and renowned of his (Professor Laycock's) predecessors in the chair of the Practice of Medicine in the University of Edinburgh, recommended stripes as a curative means for insanity, while his contemporaries adopted even harsher and severer measures, their methods of treatment were the result of the teachings of the old philosophy. That humane treatment of the insane, which they all defended and practised, followed directly upon certain principles of ethics which were deduced from experience, and these brought them into collision with the public whatever they did. Whether they restrained the personal freedom of the insane in the interests of society, or pleaded for a kindly and charitable consideration of them in the interests of justice and mercy, they were held to be equally in the wrong. Add to these ethical and social prejudices the instinctive dread and abhorrence of a violent lunatic, which was felt by most, and they could readily understand why a chorus of vituperation of "mad doctors" arose from the press and the public when a cruel and ferocious murderer, albeit insane, escaped as a lunatic from public vengeance. The antidote to all this, Professor Laycock maintained, was the reiterated demonstration of the fact that their ethical principles and practice agreed in every respect with those of the Christian religion. If they advised that persons with incurably degraded instincts be subjected to a due restraint of their freedom, was it not an act of social justice? The majority of such persons were the victims of hereditary insanity and expiated by such restriction that inexorable law, equally natural and divine, by which the sins and follies of the fathers were visited upon the children. If, in the order of Divine Providence, it was their duty to recognise that law, surely it was equally their duty to soften its pains and penalties. Such were some of the arguments by which their conduct might be justified, whenever unjustly impugned. They might feel assured that if the public mind were so enlightened as to perceive that a true mental science was in accordance with the fundamental principles of Christian morals, and that, when rightly applied, it was available to the solution of some of the most difficult and pressing problems of Christian civilization, much of the public mis-

apprehension would be obviated. But true mental science must be developed and digested before it could be effectually promulgated and applied. The learned Professor then entered upon the description of various methods with this object in view. He thought it capable of proof that mental science could be applied to legislation so as not only to diminish the numbers of the insane, but also the amount of pauperism and crime. Were they to continue wearied and helpless spectators of those sad cases of hitherto incurable dementia which encumbered the asylums by thousands? There were facts which pointed to the conclusion that the medico-psychological art had triumphed in store in that direction, for it occasionally happened that, in the worst of those cases, the clouds temporarily cleared away from the enfeebled intellect to an extent that seemed almost miraculous. What were the conditions of the brain which underlay those temporary restorations? The problem was how and when to produce those changes by art. Whatever theory they might adopt, biology applied to clinical research would help to solve those practical problems. After treating further on the subject, and considering the new doctrine of the correlations of the forces of nature, such as heat, chemical affinity, magnetism, and galvanism, Professor Laycock proceeded to treat of the better education of the medical profession, stating that it would be an advantage to the student if all the academic hospitals had wards attached to them for the reception of mental cases in their earliest stages. The knowledge that would thus be gained by the student would be available to the cure of multitudinous cases without restraint in an asylum at all. In the great public asylums, also, there is all that is requisite for scientific research, except assistants qualified by scientific training, and endowed with the zeal which makes scientific labour lightsome. He therefore advocated a suitable scientific and practical examination of candidates for asylum appointments. It must, he said, be admitted that the constitution of a psychological section in the proposed new Society of Medicine of London, was a valuable result of their organisation, and whatever might be their decision, their cordial thanks were due to the Royal Medico-Chirurgical Society, who had given psychological medicine a prominent position in their arrangements. The question was, however, would they in return for the transfer of their organisation and pecuniary support attain advantages equal to those the association now possessed? In this question Professor Laycock entered at some length, the consideration of which terminated his address.

Correspondence.

LOCAL *versus* CONTINENTAL HEALTH RESORTS.— RATHMULLAN, CO. DONEGAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have long been of opinion that many things tend to neutralise the good results supposed to flow from sending invalids to the Continent in search of health. Among the drawbacks referred to may be enumerated the fatigue of sight-seeing, the inferiority of the food, the want of the comforting influence of home and friends, and the weariness and dull uniformity of every-day life. All these conspire to exert a depressing influence upon the invalid, while the physician labours under the disadvantage of losing sight of his patient, and thus becoming, to a large extent, unacquainted with the precise condition of the case. Hence it is little wonder that both patient and physician are often disappointed at the very slender benefits derived from temporary residence abroad with a view to the restoration of health.

Such considerations as the foregoing seem to me to render it obligatory on physicians, who possess trustworthy information concerning local health resorts, to communicate such information to their medical brethren. The reports concerning such places are often furnished by incompetent or interested persons, and are not unfrequently founded on mere hearsay, so that it is difficult to determine what degree of confidence ought to be attached to them. This must be my apology for offering the following brief sketch of the physical characteristics of Rathmullan, a picturesque little village on the banks of Lough Swilly, hitherto comparatively unknown, because until very recently it has been almost inaccessible.

Rathmullan is distant twelve miles from Londonderry. Being on the opposite side of Lough Swilly, it is reached by a steamer and ferry-boats, which ply in connection with the Lough Swilly Railway. Of the entire journey, nine miles are by rail, and three by steamer or boat. The village is situated on the peninsula of Fannet, at an elevation of two hundred feet above the sea level. It has a southern aspect. Hills of gradual ascent protect it from the westerly and south-westerly winds, which are the prevalent ones. It is exposed to the southerly breeze from the Lough, and to the full influence of the sun, while the mountains of Fahan and Innishowen, on the opposite side, shelter it from the easterly and north-easterly winds. The winter climate is admirable, being mild and equable. The mean temperature and rain-fall are unknown, but the thermometer in an exposed position, on board H.M.S. *Trafalgar* (which has been stationed opposite Rathmullan for the last two years), has very rarely fallen below 32°; and in the neighbourhood of the village the frost remains a comparatively short time on the ground. The bathing is excellent, the beach being indented with sandy coves and bays, which are perfectly safe. The soil is dry and loamy, well drained, mostly in tillage, and highly cropped. The geological formation is loam on schist rock, with boulders of greenstone conglomerate, and in some parts glacial clay, or "till," two feet below the surface. Unlike many popular watering-places, Rathmullan possesses an abundant supply of excellent water. The houses are clean, well sewered, and well ventilated. The household supplies on sale are of good quality, and at reasonable rates. I have not been able to ascertain the exact death-rate, but the longevity of the residents is remarkable. Of fifteen tombstones in the old graveyard that have legible inscriptions, nine show the following ages:—

Francis Barrington, aged 75; his wife, 81. Francis Armstrong, aged 80 years; his wife, 82. James Morrison, aged 84 years. John Lockhart, 95 years; his wife, 80. William Henderson, 88 years; another, not legible, 85 years. There is at present a man living in the village whose age is known to be 111 years. He is up at six o'clock in the morning, works regularly, and is not decrepid—

"Sinks to the grave with unperceived decay,
While resignation gently slopes the way."

At the entrance of the village from the Lough stands the interesting old ruin of a monastery of Carmelite Friars, in old times inhabited by the O'Breslaus, then by the McSwines (which clan is first mentioned in Irish history in the year 1169, having been established by the O'Donnells, who brought them from Scotland), then by Andrew Knox, Bishop of Ossory, and afterwards of Raphoe. The Abbey was burned in 1618, but part of it was rebuilt and occupied by Bishop Knox, Divine Service being solemnized in the chapel till about the year 1814. There is a curious stone in the ruin on which can be traced the crest of the McSwine family—the pig with the bagpipes. Over the door can be seen the date of the repairs after the fire, with the letters A.N.K.N. S.C. 1618. The Abbey is still kept in very good preservation by the present owner of the soil, Thomas Batt, Esq., Rathmullan House. It was one of the very early churches established in Ireland on the conversion of the island to Christianity, and is mentioned often in the *Annals of the Four Masters*. It was at this church that Hugh O'Donnell (Hugh the Red) was captured. The words of Dr. Moir, of Musselburgh, are applicable to it:—

"Lonely mansion of the dead!
Who can tell thy varied story?
All thy ancient line have fled,
Leaving thee in ruin hoary.

"Thou hast had thy days of pride—
Martial squadrons ranked before thee,
Tow'ring high, and flaunting wide,
Gilded banners beaming o'er thee.

"Heroes came and tilted near,
Beauty claimed thee for her dwelling,
Evening pilgrims paused to hear
Tones of mirth and music swelling.

"Once beneath the breath of morn,
In thy halls did cheer awaken;
Dull and desolate and worn,
Thou art lone and left forsaken."

Cromlechs are frequently met with in the neighbourhood; one at Drumhallagh, of large size, called "The Giant's Bed."

At Glenallagh, three miles off, is another, called "The Stepping Stone." There are some wells in the district around which superstition has invested with sanctity, and which are in repute for effecting cures of various kinds. Tourists will find full directions, in the Visitors' Book at the Hotel, how to visit many places of rare beauty and surpassing interest.

There are several varieties of ferns growing in the neighbourhood, the maiden hair, the *osmunda regalis*, the *hymenophylli*, &c., &c. Among the many beautiful walks are extensive woods, natural and artificial, in which will be found varieties of large moths and other creatures interesting to the naturalist. The grounds of Rathmullan House, which are beautifully kept, and command a charming view of the Lough, are generally thrown open to the public by the spirited proprietor. The scenery of Lough Swilly is exquisite. It is land-locked by hill and mountain, which throw shadows on it of various tints; hence its appropriate name, which signifies "The Lake of Shadows."

I have only to add that, although my experience of Rathmullan as a health resort has been limited, I have already found it remarkable for its sanative influence in curing and alleviating consumption, in relieving laryngeal and bronchial complaints, and in producing beneficial effects on scrofulous children.

I am, yours, &c.,

WALTER BERNARD, L.K.Q.C.P.

Londonderry: July 21, 1869.

UTERINE RHEUMATISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having under my care a case somewhat similar to those described by your valuable contributor Dr. Waring Curran in the *MEDICAL PRESS AND CIRCULAR* for August 5th, I would feel much obliged if that gentleman would inform me if he considers the liniment made of aconite, belladonna, and chloroform, better than one composed of ext. of belladonna only, diluted with glycerine, and whether he would recommend the tinct. aconiti to be administered in such cases. I must confess I was much puzzled in order to arrive at a correct diagnosis of the case which I am at present treating, until I read Dr. Waring Curran's very interesting and highly valuable paper in your journal; but I am now convinced that it is one of uterine rheumatism: as yet none of the joints have become affected.

I am, Sir, your obedient servant,

AZYGOS.

COCOA AND COCOA MILLS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have long been of opinion that the more diffused use of cocoa would be desirable both on dietetic and medical grounds. The cocoa now on sale, however, even when good and pure, is too dear for ordinary use. I do not consider the moderate addition of farina and of sugar undesirable. But, if added, the exact amount ought to be stated, so that people could know what they were paying for. It would be well to fix the amount of addition, and what addition, by law, and to amerce transgressors.

But the object of this communication is not to dwell on these matters, which have already been so ably taken up in your columns, so much as to urge the adoption in every house of a cocoa mill, just as there ought to be pepper mills, mustard mills and coffee mills, for preparing the article for domestic use. The cocoa bean may be had for a shilling a pound, or thereabouts. Let it be divested of the husk or exterior, and pounded in an iron mortar, with, or without, half the weight of common sugar and half the weight of clear good starch, also, if liked, a pinch of cinnamon or cassia powder. When pounded, or it could be crushed in a conical iron mortar with a suitable pestle, for cocoa will not grind, it needs to be boiled but a couple of minutes or so, with sugar and milk to taste, to constitute a palatable and wholesome dish. This would obviate all adulteration, and secure a highly desirable and economic refreshment for every one. The South American Indians simply toney the bean, then pound it between two stones, add hot water or sometimes even cold water, I believe, and drink it. It is as easy to prepare cocoa from the bean, since it is always roasted to hand, as tea or

coffee, and I should greatly like to see the means of doing so in every house.

I am, Sir, yours faithfully,
H. MACCORNAC, M.D.

Belfast: July 5, 1869.

THE CORPORATIONS AND THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was I, not Dr. Martin, who seconded Professor Haughton's wise resolution at the General Meeting in Leeds. I did so, feeling the necessity that exists of placing the corporate bodies of the Profession in a position of power on the General Council, satisfied that if this be not done the principle of municipal government will be lost to the Profession, and we shall be handed over to a bureau of Government nominees, who, caring little for our interests, would rule us for their own. Those bodies would, therefore, be best served by making their representatives the representatives not of the Council of each body, but of the great bulk of its members, whether fellows, graduates, or licentiates.

The Profession in general should also elect their representatives, and this double representation is by no means objectionable or needless.

I am, Sir, your obedient servant,
JAMES MARTIN.

Woodview, Portlaw: August 9, 1869.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, 1869.

THE thirty-ninth annual meeting of this Association will commence this day (August 18th) at Exeter, under the presidency of George G. Stokes, Esq., M.A., D.C.L., Sec. R.S., Lucasian Professor of Mathematics in the University of Cambridge.

The Executive Committee at Exeter will elect new members and associates, on the usual conditions, and personal application for tickets must now be made at the reception-room, Exeter, which was opened on Monday last.

Gentlemen who have in any former year been admitted members of the Association may, on this occasion, renew their membership, without being called upon for arrears, on payment of £1.

In the reception-room there will be an office for supplying information regarding the proceedings of the meeting. The "Journal," containing announcements of the arrangements for each day will be laid on the table this day (August 18th), and the following mornings at 8 a.m., for gratuitous distribution. Lists of members present will be issued as soon as possible after the commencement of the meeting, and will be placed in the same room for distribution. The published volumes of the British Association will be sold in this room, to members and associates only, at the reduced prices appointed by the Council. The members' ticket will contain a map of Exeter, and particulars as to the rooms appointed for sectional and other meetings.

For the convenience of members and associates, a branch post-office (which will be available also for communication between members attending the meeting) will be opened in the reception-room.

Members and associates may obtain information about local arrangements and facilities afforded by the railway companies, on application to the local secretaries at Exeter.

The first meeting of the General Committee will be held this day (August 18th), at 1 p.m., for the election of sectional officers, and the dispatch of business usually brought before that body. The General Committee will meet again on Monday, August 23rd, at 3 p.m., for the purpose of deciding on the place of meeting in 1870. The concluding meeting of this Committee will be held on Wednesday, August 25th, at 1 p.m., when the report of the Committee of Recommendations will be received.

The first general meeting will be held in the Victoria Hall, this day (August 18th), at 8 p.m. precisely, when Joseph Dalton Hooker, M.D., D.C.L., F.R.S., &c., will resign the chair, and Professor Stokes, M.A., D.C.L., Sec. R.S., &c., will assume the Presidency, and deliver an address. On Thursday evening, August 19, at 8 p.m., in the Albert Memorial Museum a *soirée*. On Friday evening, Aug. 20, at 8.30 p.m., in the Victoria Hall, a Discourse will be delivered by

Professor Phillips, LL.D., D.C.L., F.R.S., F.G.S., &c., on "Vesuvius." On Monday evening, Aug. 30, at 8.30 p.m., in the Victoria Hall, a discourse will be delivered by J. Norman Lockyer, Esq., F.R.S., F.R.A.S., on "The Sun." On Tuesday evening, Aug. 24, at 8 p.m., in the Albert Memorial Museum, a *soirée*. On Wednesday, Aug. 25, the concluding General Meeting will be held in the Victoria Hall, at 4.30 p.m.

The sections are as follows:—

A.—MATHEMATICAL AND PHYSICAL SCIENCE.—(In the Grammar School.)—President, Professor J. J. Sylvester, M.A., LL.D., F.R.S. Vice-Presidents—Professor J. C. Adams, M.A., D.C.L., F.R.S.; William R. Grove, M.A., F.R.S. Secretaries—Professor G. C. Foster, M.A., F.R.S.; R. B. Hayward, M.A.; W. K. Clifford, B.A.

B.—CHEMICAL SCIENCE.—(In the Albert Museum.)—President—Dr. H. Debus, F.R.S., F.C.S. Vice-Presidents—Professor W. Odling, F.R.S., F.C.S.; Professor A. W. Williamson, F.R.S., Pres. C.S. Secretaries—Professor A. Crum Brown, F.R.S.E., F.C.S.; Dr. W. J. Russell, F.C.S.; Dr. Atkinson.

C.—GEOLOGY.—(In the Temperance Hall, Friars' walk.)—President—Professor R. Harkness, F.R.S., F.G.S. Vice-President—R. A. C. Godwin-Austen, F.R.S., F.G.S. Secretaries—W. Pengelly, F.R.S., F.G.S.; W. Boyd Dawkins, F.R.S., F.G.S.; Rev. H. H. Winwood, M.A., F.G.S.

D.—BIOLOGY.—(In the Episcopal Schools.)—President—George Busk, F.R.S., F.L.S., F.G.S.; Vice-Presidents—C. Spence Bate, F.R.S., F.L.S.; Edward B. Tylor, Secretaries—Henry T. Stainton, F.R.S., F.L.S., F.G.S.; Professor Michael Foster, M.D.; Rev. H. B. Tristram, M.A., LL.D., F.R.S.; E. Ray Lankester.

E.—GEOGRAPHY.—(In the Victoria Hall.)—President—Sir Bartle Frere, F.R.G.S. Vice-Presidents—Sir G. Grey; A. G. Findlay, F.R.G.S. Secretaries—H. W. Bates, Assist. Sec. R.G.S.; Clements R. Markham, F.R.G.S.; R. H. Major, F.S.A., F.R.G.S.; J. H. Thomas, F.R.G.S.

F.—ECONOMIC SCIENCE AND STATISTICS.—(In the Athenæum.)—President—The Right Hon. Sir Stafford Northcote, Bart., C.B., M.P. Vice-Presidents—Colonel W. H. Sykes, M.P., F.R.S.; T. D. Acland, M.A., D.C.L., M.P. Secretaries—Edmund Macroray, M.A.; Frederick Purdy, F.S.S.

G.—MECHANICAL SCIENCE.—(In St. John's Hospital.)—President—C. W. Siemens, F.R.S. Vice-Presidents—G. P. Bidder, C.E.; C. Vignoles, C.E., F.R.S., F.R.A.S. Secretaries—P. Le Neve Foster, M.A.; W. Smith, C.E.

The different sections will assemble in the rooms appointed for them, for the reading and discussion of reports and other communications, on Thursday, August 19th; Friday, August 20th; Saturday, August 21st; Monday, August 23rd; and Tuesday, August 24th, at 11 a.m. precisely.

The Committees, consisting of officers of sections and members conversant with the several branches of science selected by them, will meet in rooms adjacent to the section rooms at 2 p.m. this day (August 18th), and at 10 a.m. precisely, on the other days.

Gleanings in Medicine, Surgery, and the Allied Sciences.

INDIRECT OSTEOPLASTY.

Prof. Billroth, in a contribution on the results of operative proceedings for favouring the regeneration of bone from periosteum, states that, in diseased conditions of the full-grown hollow bones of adult subjects, the periosteum resembles that found in early life, in being lined by a layer of cells which may be converted into irregular and luxuriant masses of osseous tissue. This process is observed in cases of osteitis and acute periostitis, particularly in syphilitic subjects, in whom there is a great tendency to the formation of osteophytic growth. The sanguine expectations with which periosteal osteoplastic operations were undertaken have not, however, been fulfilled. In the first place, the surgeon has no power to limit or control the abundant formation of bone-cells from diseased periosteum; and, again, the newly formed bone after a time contracts like other regenerated connective tissue, and finally wholly disappears. Artificial osteogenesis may be produced in children, after resection, when the wound heals by primary intention; but it fails in adults, and when the wound remains open for some time, with profuse suppuration.

Rhinoplastic operations, in which flaps of periosteum had been detached from the frontal bone, though followed by formation of osseous tissue in the new nose, were ultimately unsatisfactory in their results, in consequence of the absorption of this tissue, and of the formation of an immovable and tense cicatrix on the forehead. The transplanting of periosteal flaps in operations for cleft palate is not approved of by Billroth, in consequence of the great difficulty of the proceeding, and of its slight utility. In cases of necrosis of the gums from phosphorus-poisoning, success has frequently attended periosteal resection when the formation of new bone was not prevented through profuse suppuration. The formation of a perfect maxillary bone must not be expected: in regeneration of the upper jaw, the antrum is lost, the bone itself is flattened, and the cheek sunken. In resection of joints, periosteal operations, in consequence of the softened and relaxed condition of the membrane, have not resulted in marked success, except in a few cases, in which they were practised on young subjects, and where healing was perfected without severe symptoms.—*Alge. Wiener Med. Zeitung, and New Orleans Med. Jour.*

SPONGE TENTS.

Knowing the fact that absolute or strong alcohol will quickly set the fibres of common sponge, after having been moulded or compressed into any given size or shape, I was led to the following quick and easy method of preparing sponge tents, tampons, &c.:—The sponge is first thoroughly moistened with water and pressed as dry as the strength of the hand will permit; then having formed it into the desired shape and size by the hand, or by pressing into a quill or any other tube or mould, it is immersed into the alcohol. If the spirit is sufficiently strong (90 to 100 per cent.) the sponge is immediately set into the given shape, which it retains perfectly after the pressure or mould is removed. It is then hard, firm, and inflexible, and may be trimmed to a sharp point or any other desired shape. To restore it to its former size and shape it is only necessary to moisten it with a few drops of water. The alcohol sets the sponge perfectly, whether the amount of compression be much or little, so that the degree of dilatation, attainable by the use of tents thus prepared, will, of course, depend upon the size after moulding and the degree of pressure used. As this process of preparation works perfectly and without delay its advantages are obvious.—*Dr. J. B. Hough, in Cincinnati Lancet and Observer.*

TEST FOR SULPHUR.

Dr. Scöhm, of Stettin, detects sulphur in organic compounds and in all inorganic sulphosalts, sulphides, sulphocyanides, sulphates, &c., by placing a little of the dry substance in a test tube, adding a small piece of potassium or sodium, and covering it with more of the dry substance. The tube is heated until the reduction is completed in a few seconds, when the tube is broken and its contents thrown into a dilute acid or a solution of nitroprusside of sodium; the former evolves sulphuretted hydrogen, the latter produces the well-known violet colour.—*Zeitschr. f. Analyt. Chemie, and Am. Jour. Phar.*

TREATMENT OF CHOREA BY THE ETHER SPRAY.

A young lad of eighteen, in May, 1868, was much frightened by a sudden near flash of lightning during a storm. In two months afterwards he showed choreic symptoms, the lower limbs first, then the upper, and in two months more he was unable to do any business. He was treated by blistering along the spine, and the administration of bromide of potassium in infusion of valerian. He became much worse, though very slowly, and got a slight attack of varicella. After its subsidence, the choreic symptoms considerably increased, he was now incapable of feeding himself, and could hardly speak. The ether spray was applied by Richardson's instrument along the spine, and 50 grammes used at a time; he was, next day, found to be much relieved. Three more applications were made, when the most wonderful improvement had occurred, the spray was continued, and at the end of eight days the patient was able to write, and was in a fit condition to leave hospital.—*Lyon Médical.*

ECTOPIUM INTESTINORUM.

A mother, 21 years of age, was delivered of a male child, in which the following state of things existed:—From an opening two inches in length at the umbilical region, $\frac{1}{4}$ inch to the right of the umbilicus, and parallel to the linea alba, bulged

out the greater portion of the intestines. Their coats were hypertrophied, and the abdominal walls were to such an extent contracted, as to allow only the admission of the small finger on both sides of the orifice. The rigidity of the abdominal wall did not allow of any stretching. It was an eight-months child, passed its natural secretions, fæces and urine. In the morning it vomited bile, and in the afternoon nursed at its mother's breast; its pulse was regular, as was also its respiration. The portions out were made up by the duodenum, jejunum, and ileum of the small intestines, and the colon and a portion of the rectum of the large intestines. The child died the day after its birth, having lived exactly 21½ hours.—*Geo. Fredigke, Chicago Medical Examiner.*

A REMARKABLE CASE OF TETANUS.

M. NEVEN DEROTRIE details a remarkable case of tetanus in childbirth, marked by closure of the teeth, impossibility of swallowing, general rigidity, opisthotonos, tetanic contractions, risus sardonius, and death in sixteen hours. The woman was poor, badly circumstanced, in a cold damp room, and a bad bed. Besides, though the labour was not protracted, the placenta gave some trouble by its adherence; it was torn,—so much so, that it was probable some portion remained in utero.—*Journal de Médecine de L'Ouest.*

Legal Intelligence.

ATTEMPTED FRAUD ON A RAILWAY COMPANY.

NORTHERN CIRCUIT, MANCHESTER, AUGUST 12.

(Before Mr. JUSTICE HANNEN.)

The civil business having been disposed of, his Lordship then tried the case of Henry Ford, who was placed at the bar charged with having attempted to obtain £4,000 from the London and North-Western Railway Company, by false pretences, in September last.

Mr. Pope, Q.C., and Mr. Jordan conducted the prosecution; Mr. Cottingham defended the prisoner.

This case disclosed a very ingenious and daring attempt at fraud on the part of the prisoner, founded on the great accident at Abergele, which occurred on the 20th August last. It appeared that on the 2nd of September the company received a letter from a Mr. Fox, the prisoner's attorney, to the following effect:—

"Gentlemen,—Our client, Mr. Henry Ford, of Patricroft, was in the train at the time of the accident on the Holyhead Railway, and was a first-class passenger, having a through ticket from Chester to Dublin. He was very much shaken and injured by the shock, and he has found it necessary to consult his surgeon, who says he is suffering from concussion of the spine, &c.; and that he must remain in bed some time to give him any opportunity of recovering. Mr. Ford will claim compensation from the company in respect of his injuries, but it is impossible at present to state the extent and nature of them. If you wish the surgeon of the company to see Mr. Ford, please put him in communication with us, and we will arrange for his doing so."

In consequence of this letter, the prisoner was seen by one of the officers of the company, and also by several medical men, and to them he appeared to be suffering most seriously, and apprehension was entertained whether he would be able to walk again for years. He made a claim for £4,000 compensation, and an action was commenced by him, which would have been tried at the last assizes, but, as the plaintiff stopped short in his supply of funds, the record was necessarily withdrawn by his solicitor. He absconded from the neighbourhood soon after, on the 12th of April, after perpetrating another fraud on the strength of the same accident, and it gradually became clear that the whole story was an imposition, and that he had neither been near the scene of the accident, nor ever been suffering from any injuries whatever. He had stated to the company's officer—in contradiction, apparently, of his solicitor's original letter—that he was riding in a second-class carriage, which was not padded, but it was proved on the trial that there was no carriage in the train that was not padded. It was further proved by a butcher at Barton, the place where the prisoner lived, that he was seen by him in a house there on the day of the funeral of a certain Mrs. Allen, and other witnesses proved that that was on the 20th August, the day of the acci-

dent. A policeman at Barton also proved finding the prisoner's house-door open on the night between the 21st and 22nd of August, and rousing the prisoner up, and that he came downstairs to fasten the door, and was able to walk and appeared perfectly well. He was perfectly well, and free from any trace of injury when he was taken into custody on the 3rd of last July, upon the other charge of fraud against him; and, when told that the company would prosecute him, he asked if there was no possibility of an arrangement, stating he had been told he should get 12 or 15 years if convicted.

His learned Counsel addressed the jury in his behalf; but they immediately convicted him.

His Lordship, in summing up, said that although fraud was frequently committed in connexion with railway accidents, and impositions were practised, he feared, upon railway companies, they were rarely attempted under circumstances of such gross impudence as this. It was clear that the prisoner was not present at the time of the accident at all, but had endeavoured to trump up the appearance of a person who had been injured, and so successfully, that, if it had not been from a failure of his funds, he would have made his appearance in court to support his fabricated case by perjury. Under the circumstances, the sentence upon him was that he should be imprisoned for 18 months.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen have been elected Fellows of the College—viz., Messrs. John Whipple, date of diploma of membership March 5, 1824; and W. J. Square, both of Plymouth, May 11, 1835.

NEARLY all our daily contemporaries are devoting space to the subject of vaccination and the opposition it has recently met with. The *Telegraph* of Monday remarks that it will not undertake to decide between the advocates of vaccination and its opponents, but considers it is quite clear that the time is come for an authoritative and conscientious re-inquiry. Let us, then, have no professional begging of the question, and no dogmatical decisions; but let the truth be carefully told about the way in which the lymph is at present obtained for the poor, the recorded effects of its immission—the alien diseases observed to follow from its use—the apparent successes and acknowledged failures of the prophylactic—and, in a word, all the scientific facts of the matter. The question is of enormous social import, and probably, if examined by able minds, would throw great light upon profound problems of natural science. This is no age in which a thing can stand merely because it is on the statute-book; neither is it a time when we should allow a national safeguard to be broken through at the whim of ignorant or crotchety persons.

OPPOSITION TO THE VACCINATION ACT.—On Saturday, at the Thames Police Court, an ignorant woman, who objected to vaccination "on principle," and who had been previously fined, was convicted in a penalty of 20s. for refusing to have the operation performed on one of her children. Rather than pay the money, the defendant went to prison. At the Greenwich Police Court the parochial authorities of Rotherhithe proceeded against several persons for failing to have their children vaccinated. One of the defendants, who carried an infant in her arms, said she was desirous not to have the child vaccinated, a former child, a girl, who was perfectly healthy before being vaccinated, having immediately afterwards become covered with eruptions over the whole body, and for fifteen weeks she had to carry it to and from Guy's Hospital, where it died. The magistrate said the law would not permit parents to keep their children from being vaccinated, and it was their duty within the time prescribed to have it done, or to obtain a medical certificate that the child's state of health was such that it was unsafe for the operation to be performed. The objection to the system of vaccination could not be allowed, and in dealing with the cases before him he should adjourn them to a future day, when, in the event of the law not being obeyed, or medical certificates obtained, he should impose penalties.

CRUELTY TO A LUNATIC.—A shocking case of cruelty to a lunatic has just come to light in Leicestershire. In consequence of certain information, a gentleman sent by the Commissioners of Lunacy, accompanied by Mr. J. Buck, medical officer of the Leicestershire and Rutland Lunatic Asylum, several magistrates, and a police superintendent, visited a lodge-house in the parish of Sheepshed, near Loughborough, occupied by a small farmer named Henry Black. There a

shocking spectacle was revealed to them. A poor demented creature, seventy-four years old, with his hands fastened in front of him by handcuffs and his feet encircled by manacles, occupied a small apartment, being chained to the wall of a room. From the keeper Black it was elicited that the wretched prisoner's name was Bagley Wild, a relative of the late Mr. Wild, J.P., of Costock, Notts. He had been under Black's care for thirty years, and previously in another man's custody for a like period. During the whole of this time he had been kept chained up in the manner described. Black has been receiving 1*l.* a week for his charge, and it is only fair to state he was found well nourished, healthy, and clean. He was never, it seems, relieved from his chains, asleep or awake. When taking his meals he was fastened to a chair, and when he retired to bed at night he was fastened by the chains to the bed, while the handcuffs encircled his wrists. He has now been removed to the Leicestershire and Rutland Lunatic Asylum.

AN OPIUM EATER IN THE WITNESS-BOX.—An opium eater was being examined in the Bombay High Court on Saturday. At about four o'clock his powers of endurance seemed to fail him, and he told the Chief Justice, who was on the bench, that he was an opium eater, and wished to get away to eat his daily quid. The Chief Justice: Unless I am satisfied that it is dangerous to his health not to eat it at this time, I will not allow him to do so. If a medical man comes and tells me it is dangerous to his health that he remains here he may go, but not otherwise.—Mr. Marriott (who was examining the witness): I believe the want of it produces very great prostration.—The Advocate General (who was to cross examine): It may affect his evidence (a laugh).—The Chief Justice: Tell him that other witnesses may suffer here from the want of something they wish to take at certain hours. If he gets any medical evidence that it is dangerous to his health I will allow him to go.—Mr. Pigot (with Mr. Marriott): He can do without it for an hour, surely.—The Chief Justice: Yes, I think so; go on.—The witness was here supplied with a chair, and went on with his evidence for a time, but afterwards, in reply to a question, witness said: I don't know. It's my time of eating opium, and I am not in my senses now—I feel giddy. I don't know what I am about now. I know that opium-eaters eat at regular times, and they never fail to take it.—The Chief Justice: Well, but other people never fail to take other things at regular times, and still we don't allow them.—In reply to the Court, the interpreter stated that the witness had hitherto been answering very well, and so the examination proceeded. Then at the commencement of the cross-examination, the Advocate General piled up the agony on the luckless witness by asking him if all the evidence he had given was part of the result of his dreams after eating opium—to which witness replied that the cause of his present physical difficulty was not opium, but the want of it.—*Bombay Gazette.*

SHOCKING ACCIDENT AT SULPHUR SPRINGS.—The Paris correspondent of the *Star* says:—"A sad catastrophe occurred last week at the sulphurous springs which attract so many visitors in summer to the Lake of Enghien. A workman whose business it was to clean the pipes for the conveyance of the spring waters to the drinking establishment, fell into the principal reservoir. A stoker named Delune, who happened to witness the accident, stooped down over the sulphurous water, and, suffocated by its fumes, fell into the reservoir. Seven other employes of the establishment, attracted by the crowd which had assembled, successively in attempting the rescue of their predecessors, followed their example and fell into the reservoir. By the time all these victims had disappeared, the lookers-on organised a more rational system of rescue. The seven bodies were extricated from the reservoir, and three in time to restore them to life. The workman whose fall had caused the subsequent accidents was dead, as also Delune, a mechanic named Legraud, and Francois, one of the servants belonging to the baths."

THE CONTAGIOUS DISEASES ACT IN GARRISON TOWNS.—Dr. Stuart, who has been appointed medical officer for Chatham and Woolwich, has been energetically at work with the great social enemy with the most successful results, so that the cases now average less than five per cent. The Lock Ward at the Herbert Hospital is frequently empty. The doctor receives a maximum salary of 700*l.* a year, with travelling expenses, and is, with Inspector Crouch, most assiduous in carrying out the requirements of the Act of 1866, which, so far as garrison towns are concerned, has been found to work most beneficially. The number of prostitutes about the streets of Woolwich is 250.

HERMINTHOLOGY.*

(Communicated to the MEDICAL PRESS AND CIRCULAR by G. GASKOIN, Esq.)

It is now two years past since the late Councillor Griesinger, of Berlin, encouraged me by letter to search in the urine of patients affected with intertropical hæmaturia for the eggs of the *distomum hæmatobium* or *Bilharzia hæmatobia*, a nematoid, which, according to the investigations of Bilhazz (its first discoverer) and those of Griesinger and others, was observed in individuals who had died of hæmaturia or chylous urine in Egypt.

Agreeably to this request I examined carefully a number of patients affected with hæmaturia here in Bahia without ever once meeting with any ova. I did not believe they could have escaped my observation had they existed; on the contrary, I became more and more convinced that if the hæmaturia of Egypt, and of the Cape of Good Hope, and also of the Isle of France, is the consequence of *distomum hæmatobium*, the hæmaturia that we get in Brazil is a complaint with a different etiology.

The symptoms of this ailment, according as it is seen in Africa, are in many respects different from the hæmaturia observed in Brazil. There are particular circumstances in which they differ. In Africa the complaint is very frequent in children, but in Brazil I do not remember ever meeting with a single case of this chylous urine happening to a child. In Africa the complaint is more frequently accompanied with true hæmorrhages, and in many cases with sand in the urine, which, as far as I know, has never been observed in Brazil.

The symptomatology of one as of the other form of complaint is to be found in the work of Rayer, "*Traité des Maladies des Reins*," tom. iii, p. 397, Paris, 1841.

* Preliminary notice on worms, of a species not yet described, which are met with in the urine of patients suffering from intertropical hæmaturia in Brazil, by Dr. Wucherer, practising in Bahia.

The history of a young Brazilian,† who, while in Europe, was examined by Messrs. Caffre, Orfila, Rayer, Astley Cooper, Marshall Hall, Clark, &c., will bring before the reader a faithful picture of the complaint such as we find it here in Bahia.

Thus, although I am compelled to confess that the symptomatology of intertropical hæmaturia as observed in Africa and Brazil have many points of resemblance, I must insist upon the fact that I have found it quite impossible (in spite of repeated investigations made with all desirable accuracy) to find the ova of the *distomum hæmatobium* in the urine of any patients with hæmaturia examined by me. These ova are of such dimensions and also of such especial configuration that I do not deem it possible that they could have escaped the apprehension of my visual faculty.

However, I have now to relate a quite unlooked-for result of my examinations. On the 4th August, in 1866, I had to examine the urine of a woman who was a patient of a friend of mine, Dr. Silva Lima, in the hospital of the *Santa Casa de Misericordia* in that city. The urine was of milky aspect, and contained some reddish or cherry-coloured (*ginja*) coagula; and its specific gravity was from 1005 to 1012, and its temperature 12°, 5 Centigrade. Even when filtered it remained almost as milky as ever. No new coagula were formed by boiling or by nitric acid. On examining a particle of the coagulum with the microscope, I found, besides several crystals of triple phosphate, epithelial scales, red blood corpuscles, fat and mucus corpuscles, vibrones, &c., and some filiform worms with an obtuse extremity and the opposite one very fine.

In the obtuse extremity of the animal a small point was distinguishable; but it was not possible to learn if it was an orifice. The body was transparent, or appeared to contain a certain granular mass, but it was not possible to distinguish its structure. Suspecting that these worms were of casual occurrence in the urine, I made the patient urinate at the moment of examination in a glass vessel that was scrupulously clean. Even then I got the same

worms. Still, as I had examined the urine of many who had hæmaturia without seeing anything of the sort, I did not then give a due importance to my discovery. I may be permitted to say that I have notes of six cases that I had examined up to that date—some of these were patients of Dr. Silva Lima, some of Dr. Paterson. I was highly desirous of finding the ova of the hæmatobium, and being disappointed in this particular, some weeks passed before I examined the urine of patients with hæmaturia. On the 9th October of this year Signor Santos Pereira, then student, now doctor of medicine, requested me to examine the urine of a lady he had under treatment for hæmaturia, and I was not a little surprised to find here present the same worms that I had observed in the case above referred to under care of Dr. Silva Lima.

The circumstance that I had found these worms each time in the urine of women caused in me mistrust that they proceeded from the vagina, even though there was not the smallest resemblance with the worms which are often met from this source of the species of *trichotomos vaginalis*. But it was not long before a male subject appeared who was affected with the same complaint.

This patient passed water, while under view, in a glass vessel, which was then set apart so that the urine might settle. It was slightly turbid; it had the greatest resemblance to a pretty clear milk serum; it had a weak urinous smell, and did not appear to contain any blood. After half an hour there seemed to be formed a large transparent coagulum, which only was seen when I attempted to pour off the urine. On raising a fragment of this coagulum with a forceps the liquid part dropped away from it, and in proportion to this loss the coagulum was opaque, till at last there only remained a tattered film like the pellicle that forms on the surface of the milk bowl.

On examining a particle of the size of a pin's head in the microscope, the same worms were readily discovered which I have seen in the two other cases; they were alive, and executed undulatory movements of an energetic character, the same, in fact, as I had seen before when I examined the yet recent urine of the patient of Dr. Silva Lima in the year 1866 as aforesaid. With a combination that gave a multiplying power of 400 diameters, it was not possible for us to discover the organisation of these worms. They were in breadth of the diameter of a white blood corpuscle, and 60 or 70 times longer. The urine did not contain red corpuscles of blood, but it did many white corpuscles, apparently leucothymatous, and many blood globules. In the course of a few days I had occasion also to re-examine the urine of Dr. Santos Pereira's patient, as well as of the male patient. Both were improved, and the worms were gradually becoming more unfrequent, so as with some difficulty to be found.

With a suspension of the treatment the man had a relapse, his urine became once again milky, it coagulated, but did not present the same abundance of worms as at first.

During these few years past I have had many times to examine with the microscope the urine of patients with different diseases both in my own clinique and in that of my colleagues, and I never met with these worms except in the three cases of hæmaturia above referred to. The reason why I did not discover them earlier is doubtless because at first I omitted to examine the coagula, since the ova actually occur in the deposits from the urine, it being precisely in the coagula that they are found in most abundance.

Unfortunately, I had not yet had before me the last part of the work of Dr. Leuckart on Human Parasites, that, namely, which treats of nematoids; but in a list of human entozoa which occurs in this work there is no worm mentioned which is similar to that which I observed, nor is it shown in the list of Dr. Spencer Cobbold, or in the works of Kuchenmeister and Davaine. It would be rash to hazard any final opinion on the occurrence of these worms in cases of hæmaturia or on their psychological significance if they have any pertaining to them; and on this

account I refrain from this until I have examined the body of some patient with hæmaturia, which, up to this time, I have not found possible. I hope, however, that this communication may prove an incentive to colleagues more ingenious and privileged than myself, to undertake the elucidation of a complaint which, as yet, is without an etiology, and, in the present day, quite an enigma.—(From the *Gazeta Medica de Bahia*.)

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.

JERVIS STREET HOSPITAL.

(From the Notes of Mr. MULLIGAN, Resident Pupil.)

Enormous Hypertrophy of Breasts, necessitating Removal of One Organ; the Operation followed by the Reduction in Size of the Remaining Breast.

MARY M., æt. twenty, an unmarried girl, of delicate appearance, was admitted into Jervis street Hospital under the care of Dr. McSwiney, on April 7th, 1869, suffering from enormous enlargement of both breasts.

She had always menstruated regularly, and enjoyed good health, but had scarcely any development of the mammary glands until about a year before her admission into hospital. The breasts then suddenly began to grow large, her changes meantime occurring regularly, and her general health remaining good. About six months after the first commencement of their growth, the breasts became so large as to cause her much inconvenience, owing to their great size and weight.

When admitted, the breasts were found greatly enlarged, elongated, and dependent; their surface was smooth and regular; the nipples were scarcely visible; and careful examination revealed that there was evidently present a simple hypertrophy of the mammary glands. The patient was in a very exhausted condition from the constant dragging and weight of these enormous masses, which were so large as to interfere with her activity, and prevent a healthy amount of exercise. She had previously been under the care of several hospital surgeons, who had not succeeded in affording her relief, and the hypertrophy continued to increase.

Every effort to procure absorption of the glands was made, the iodide of lead ointment was applied externally, and numerous medicines, including the iodide of potassium with bark, were exhibited without avail, until the girl left the hospital without any benefit. In three weeks, however, she was obliged to return, as the breasts were still increasing; and, as all other treatment had been found useless, and as the girl was actually sinking from the exhaustion and irritation consequent on their great size, Dr. McSwiney proposed that one of them should be removed, hoping that the other might then decrease in size. Agreeing in this, Mr. Stapleton, on the 22nd of July, having previously elevated the right breast, in order to drain the blood from it, proceeded to remove it by two semi-elliptical incisions. It was readily detached from the surface of the pectoral muscle.

The mass weighed six and a-half pounds, was composed of a number of lobules, and was shown by the microscope to be merely a hyper-development of the true gland tissue.

The wound healed rapidly, union by the first intention taking place, and no constitutional disturbance occurring.

The opinion that the left breast would diminish in size after the removal of the right was completely verified; it decreased in a remarkably rapid manner, its diminu-

tion being evident to all who saw it, and affording great relief to the girl herself, who was discharged from hospital August 19th, 1869, with her breast showing every sign of resuming its normal proportion, which, indeed, it had nearly done.

MR. STAPLETON'S CLINIQUE.

Fracture of Patella.

Mr. Stapleton drew attention to Thomas M., æt. fifty-five, who had been admitted into hospital six weeks previously, suffering from a transverse fracture of the left patella. He wished to impress on his class the necessity of attending to the posture of the patient in the treatment of these cases, and of placing him in such a position as to relax the muscles attached to this bone. The knee-joint should be extended, the leg elevated, and the body raised from the hips up, so as to relax the muscles which tended to displace the upper fragment.

He was in the habit of treating these cases by posture, and by the application of pads of lint above and below the broken bone, which were drawn together by a long strip of adhesive plaster extending from the middle of the thigh, across the front of the patella, and down to the ankle. Transverse strips of plaster of sufficient length to half encircle the limb should be then applied above and below the knee-joint, so as to prevent the displacement of the pads, or the liability of the long anterior strip to start forwards.

The success of the method he always found sufficiently good; and in the case before them the union between the fragments was very close, and the result as good as could be obtained by any of the more severe methods of treatment.

MERCER'S HOSPITAL.

CASE OF CONTRACTED MOUTH, OPERATED UPON SUCCESSFULLY.

By Mr. MORGAN, F.R.C.S.I.,

Surgeon to the Hospital, &c., Professor of Surgical and Descriptive Anatomy, R.C.S.I.

THE difficulty of preventing contraction from cicatrization in parts already condensed by diseased or ulcerative action, and particularly when in the neighbourhood of natural orifices, is well known in surgical practice. When occurring at the mouth, this contractile tendency is a source of great trouble, not only by reason of the deformity, but from the consequent difficulty of speech and the great inconvenience in taking food—the use of solid aliment being, in fact, all but precluded.

The subjoined case illustrates a successful operation under circumstances of unusual difficulty. The deformity was of old standing, and the parts had suffered from several outbreaks of disease and ulcerative action; the mouth and parts around had now been the seat for many months of lupoid ulceration, mixed with a syphilitic taint, which had caused, in the process of cicatrization, great condensation of the lips and cheeks generally, and adhesions between the cheek and the gum of the upper jaw. As will be seen by the woodcut, the mouth was reduced to the smallest dimensions, and would absolutely not admit the point of the little finger; there was also a hardened papillary growth on the lower lip. The patient had not taken any solids for months, and had to use a kind of little ramrod to introduce his food through the narrowed and immovable opening. His speech was necessarily imperfect, and any continued conversation impracticable. The patient was thirty-five years of age, much broken down in health and spirits, and urgently sought relief from the gradual narrowing of the orifice and from the ulceration which still existed.

He had suffered from exfoliations of the forehead and osteoscopic pains, and the tongue was painful from ulcerations, which could not be treated by any ordinary local stimulation.

Large doses of iodide of potassium were administered; a tongue bath of black-wash, used twice daily, and good diet ordered.

After five weeks the ulceration of the lips and mouth had much improved, and when the healing process had completed itself I adopted the following procedure in order to ensure as much as possible against contraction:—I passed a full-sized Chassaignac's drainage tube through the cheek, about three-quarters of an inch from the angle of the contracted mouth, and retained the tube in this position, acting as an issue till cicatrization had taken place around, and a fistulous orifice, in fact, formed; this occupied about fourteen days in its production. I then from this point carried two incisions towards the mouth, and removed a rather wedge-shaped piece, its apex being at the fistulous opening produced. This was followed by a satisfactory result; the parts gradually healed, but some contraction nevertheless occurred, to about one half. When this side was tolerably healed I adopted a similar proceeding at the other, but I took care to increase the distance from the angle of the mouth after fourteen days, when I found the tubing had sufficiently established a fistula, I took away also a wedge-shaped piece, as at the other side, and adopted every precaution to prevent further narrowing. I gained on this side more than half the distance. The mobility of the jaws was perfect; the patient had lost many of the teeth by ulceration of the alveoli, and the integument over the chin was drawn as tightly as it is possible to conceive.

The comparative illustrations of the condition before and after operation will show the great narrowing that had taken place, combined with increased density, almost of a cartilaginous firmness, and the improvement gained.

FIG. 1.—Before Operation.

FIG. 2.—After Operation.

The repair of the general health, and the rapidity with which he regained his weight and strength, were remarkable in this patient; he felt so strong shortly after being operated on as to leave hospital and go to work.

The use of the tubing, and the formation of a fistulous point to act from and ensure a permanent angle to the lips, I found most satisfactory as the main cause of a perfect result to the patient, the tendency to contract and curtail the natural opening was most persistent.

Transactions of Societies.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

A MEETING of this society was held on Wednesday, the 4th inst., Dr. Gordon, C.B., Deputy Inspector-General of Hospitals, in the chair.

The honorary secretary read a paper on the "Vapour Bath" by Surgeon Lamprey, 67th Regiment, in which the author described the apparatus of Dr. H. Lees for administering mercury by this means, and entered fully into the advantages of the method of treating particular forms of disease. He detailed a very simple mechanism extemporised by himself for administering medicated vapours which acted quite as well as that of Dr. Lees, and had the additional merit of being much less expensive.

Dr. Evans, late senior house surgeon in the Royal Portsmouth (civil) Hospital, read a paper on the operation of the Contagious Diseases Act in Portsmouth, in the course of which he remarked that lock wards were first established in that hospital so far back as 1856, the beds in which were occupied by patients voluntarily applying for relief, but that so slight was the effect produced upon the prevention of disease by this arrangement, that so lately as the first half of 1867 more than fifty per cent. of those who under the Act were subjected to examination were found to be infected. Since that time, however, a marked decrease has taken place in the prevalence of disease among men as well as among women in Portsmouth and Gosport, and the type of that which prevails is much less severe than it was prior to the Act being enforced. He had no means of estimating the number of women who in former years would have come under the Act had it existed, but at the present time their proportion in these towns is only a fraction under five per thousand of the general population, and that about one-seventh of all are suffering from disease. He gave many interesting particulars with regard to the class of persons to whom his observations applied, stating among other matters that their liability to disease was greatest during the early period of their abandoned life, that it decreased thereafter, and that some few remained free from specific maladies, although other affections were found to be so prevalent among them it may be questioned if any be in all respects healthy. He gave some statistics of the manner in which women whose history could be traced were disposed of on being discharged from hospital, and stated that about twenty per cent. were induced to return to their homes or to enter institutions of various kinds, but that in a large proportion of those the improvement was only temporary, and that sooner or later they returned to their abandoned habits. Few among them, even among the better style, were able to write, and so far as his observation enabled him to judge, manual work was distasteful to all. As to the causes which led, in the first instance, to the downfall of these women, Dr. Evans considered domestic unhappiness among the chief; thus unkind stepfathers and stepmothers had, in his opinion, driven many girls upon the streets. Others were systematically deserted or neglected by their parents, and thus from childhood scarcely knew any other life than that in the streets; and some, although happily a small number, consisted of servant girls out of place or otherwise reduced. Beyond these, however, there seems reason to believe that there exists a class who are difficult to reach by the administration of the Act, that a considerable number of young women having ostensible means of living and working at various occupations during the day are thereby exempted from its operation. He observed that the medical men intrusted with the duty of performing the professional examinations did not treat those whom he found diseased, but that they were placed under the charge of the ordinary staff of the hospital. He was of opinion that the system of classification in hospital should be more effectually carried out than it seems to have hitherto been; thus he would have the younger women more completely separated from the older than is at present customary, by which arrangement he considered that moral influence would be more effectually exerted upon them than is practicable while they remain among their more hardened sisters. He would also suggest that small wards,

capable of containing four or five patients, are better suited to the purposes of a lock hospital than those capable of containing more considerable numbers, as their inmates would thus be by so much less exposed to example and precept of their companions than when congregated as at present. The plan of having a regular hospital dress for the lock patients is, he considered, a good one, as it prevents them from absconding, and he would, in the case of similar hospitals that may hereafter be erected, have them placed in the country and at some distance from the town; one good result anticipated from such arrangement being that the inmates would the more completely be removed from the inconvenient visits of their friends and from associations connected with their manner of life.

In the course of the conversation which followed the reading of Dr. Evans' important paper it transpired that while a considerable number of diseased women finding themselves liable to be inspected suddenly migrate to places where they are strangers, some under similar circumstances came to Portsmouth. It by no means seldom happens that others come to this as well as to other stations at which the Act is in operation for the very purpose of being taken up by the police and sent to hospital. The mortality among them is by no means so great as might be anticipated; only four of those treated in the lock-wards have died, and none by disease peculiar to their habits. On the other hand, however, some, after being retained under treatment for lengthened periods, had to be discharged from hospital as incurable. These had a protective certificate given to them, and were liable to imprisonment if found practising their vocation. In connection with the subject of reformatories and homes for those who desire to avail themselves of such places, various particulars were given regarding institutions of this kind at Portsmouth and elsewhere; their tendency being to show that although many of those who resort to them return to the streets, they are, nevertheless, a very valuable means of restoring such as really desire to abandon a life of misery and vice, and that the measure of their success is in proportion to the discretion of their management.

The Chairman thanked Dr. Evans for the carefully prepared paper he had read, and which in some respects might be considered in connection with an article on the same subject in the *Westminster Review* for the present month. Referring to what had been stated in regard to the comparative freedom of the classes in question from general diseases, he said they were in accord with observations made in continental cities. He believed that so long as the Act is in reality only made applicable to women as it now is, its operation must necessarily be imperfect; that if it be intended to stamp out the disease this can only be effected by applying the Act over the whole kingdom to all classes equally, and to men as well as to women. He was of opinion that as at present administered it bears unequally, and at the same time unfairly upon women as compared to men, and that the one as much as the other should be liable to examination, and, if need be, compulsory treatment, on information being formally lodged that they are suspected of communicating infection. The Act should be administered through one organization, instead of being so as at present by various agents, and a medical superintendent should be appointed, not only for the purpose of performing professional examinations, but also treating all patients admitted into the lock-wards. He regretted that no ready means appeared to be available whereby the numerous homeless children who frequent the back streets and ramparts of the town could be provided for, or by which punishment could be brought home to parents who habitually neglected their children; and observed that in one respect, at any rate, an example might be borrowed from the other side of the Atlantic. In one American state, if not in more, and recently in Canada, a proposal has been made, by enactment, to render seduction penal. Were a similar Act passed in England it is easy to conceive that much misery and much infamy would be averted among the female population whether of our towns or agricultural districts.

The proceedings then terminated.

QUININE IN SEPTICEMIA, &c.

It counteracts septicæmia and the abnormal immigration of blood-globules in raw or exposed membranous or parenchymatous organs. It stops the movements of the white corpuscles; prevents the increase or new formation of cells, and exerts a controlling influence over dilatations of the blood-vessels.—*Schmidt's Jahrbücher.*

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 144.)

Sir, I was rather astonished when I heard it put forward by some of my critics, that the mortality in the extern cases attended from the Dublin Lying-in Hospital amounted to 1 in 61 deliveries. I was aware that this branch of the institution had not been much encouraged, neither had the records of cases been very regularly kept. As a governor of the hospital I drew, about two years since, attention to the necessity of encouraging the out-door attendances and of keeping a more accurate record. I therefore applied to the Registrar for a report of the last year's deliveries, in order to compare them with Dr. Johnston's year of the hospital, when it was, in his words, as healthy as one could almost desire, and find by it that in the year ending March 31st, 1869, the extern attendances amounted to 147, with but 1 death. The mortality within the hospital for the same time amounted, as we have seen, to 1 in 45, or three and one-fourth to one of that without the hospital; and be it recollected, that this is the year in which the improved condition of the hospital, commensurate with Dr. Johnston's mastership, has been dwelt upon. Would we could even effect this saving within its walls.

We now arrive at Dr. M'Clintock's strictures upon my paper, and as this gentleman occupied an hour and forty minutes in developing them, you must bear with me as patiently as you can in the time required for their refutation. Our time will not, however, I trust, be misspent, as, from his numerous objections, his ingenuity, and his peculiarly pungent and asseverative manner of attack, I am quite aware that his observations produced a marked effect upon his hearers. I shall not follow his example, however telling as it may have been, of assuring you before doing it that I am about to annihilate him for ever. I shall not seek to forestall your plaudits by declaring my intentions of conquest which, like those of the boastful opponent of Tekeli, may fail to be realized in presence of the adversary. But I shall ask your calm attention to my reply, free of all favour, affection, and prejudice; as, in replying to this gentleman's somewhat bitter attack I shall be also meeting the objections of several others of my critics, whose arguments he has repeated and amplified. It is therefore, I repeat, the more necessary that a patient, considerate, and candid hearing may be accorded to me.

The spirit in which Dr. M'Clintock approaches the great subject that engrosses us (the means of reducing the admitted mortality in our lying-in hospitals) will be best understood by introducing him to you as the propounder of a novel and startling principle applicable to lying-in-hospitals, and one which he enunciates in the language of Drs. Bristow and Holmes, "that a high death-rate indicates, as a rule, that an hospital fulfils efficiently the purposes for which it was designed, and that a low death, on the other hand, indicates, *ceteris paribus*, comparative inefficiency." Why, sir, this principle, even as applied to general hospitals, admits of great question; but its application to lying-in hospitals I shall not trust myself to characterize. Such an assertion might be made in the heat of debate, but furnishes no excuse for a gentleman in his calm moments deliberately putting forth such a maxim as this before a society of enlightened physicians, namely, that "the principle enunciated (in these quotations) applied with little qualification to maternity as well as surgical or medical hospitals." We shall hear presently what Dr. Stokes says on the subject of

labour as a natural process. How the learned Regius Professor must have shrunk, horror-stricken, from the avowal of such a principle!

After enunciating this paradoxical and shocking dogma, Dr. M'Clintock wanders off to descant upon reliable estimates of mortality in women in their own homes. But we shall not require him to go out of the four walls of the hospital in which he resided for ten years, to prove the case against himself. We shall not require to compare hospital with private practice to refute it. Let us take any period for which the hospital was free from metria, for a sufficient time, to give a fair average of deaths by the accidents of labour and diseases, independent of metria. Say the last three years of Dr. Collins's, and the first year of my mastership; that is four years, from 1830 to 1833 inclusive. In these four years there were 8,844 deliveries and 48 deaths, or 12 annually; that gives 1 death in 192. Now let us take, say the last four years of the hospital, from 1865 to 1868 inclusive. The deliveries were 4,574, the deaths 149; that gives 1 death in say 30½. The result of the comparison of the hospital with metria against the hospital without metria is to give 5½ unnecessary deaths out of every 6 that occurred in the last four years, as compared with the period 1830 to 1833. Now, does Dr. M'Clintock mean to tell this intelligent Society that that excess of death-rate in the same hospital, under identically similar circumstances in every respect save one, the presence of metria, furnishes us "with grounds to draw his inference, and satisfy him with its foundation?" "That a high death-rate indicates as a rule that the Dublin Lying-in Hospital fulfils efficiently the purposes for which it was designed, and that the low death-rate of Dr. Collins's four years, on the other, indicates (*ceteris paribus*) its comparative inefficiency in his period?"

Dr. M'Clintock triumphantly collects and recapitulates, what I had already given in my tables, the instances in the Lying-in Hospital in which the largest number of patients that had been delivered with the smallest death-rate; and after dwelling upon these as disproving my third proposition, he concludes by alluding to Dr. Labatt's most crowded period (the very one I had adduced as confirming my position) in these remarkable words:—"This was certainly enormous cohabitation, and it did certainly breed an epidemic puerperal fever, but there were three years of gestation before it appeared." Here we have the one grain of wheat in the bushel of chaff. But Dr. M'Clintock is in error in saying there were three years' freedom from puerperal fever at this period—there were only two, 1815 and 1816, and these he should have mentioned (a fact that he, as master, could not have been ignorant of) were the very two years that the auxiliary hospital was added, and the crowding lessened. In 1817 the mortality rose again from 1 in 182 to 1 in 108, and in the next year to 1 in 62, whilst in 1814 it had been 1 in 100, and in 1813 1 in 40.

After such an admission, which common sense and common honesty extorted at Dr. M'Clintock's hands, followed by my commentary of the addition made to the hospital, which he suppressed, what becomes of his statistics collected from my tables with such assiduity, and his cavils as to the comparative mortality in New Ross and Waterford Cottage Hospitals? Sir, Dr. M'Clintock might possibly have better consulted the interests of our common humanity, as he certainly would have done his own consistency and good taste, if he omitted his charges of *exaggeration* and *unsoundness*, dealt so unhesitatingly against me, in the very same sentence in which he admitted that I had made a *strong* case against larger hospitals in my mode of dealing with them, and when he still further "*conceded really* a greater mortality amongst women confined in these institutions as compared with the aggregate of women confined in their own homes."

Why, these two points include the whole principle for which I have been contending.

My third and fourth propositions are the undeniable logical corollaries based upon these. Our eight nights have been occupied in testing the accuracy of these two propositions; propositions which, in slightly altered language, Dr. McClinton himself admits, and, as we shall see afterwards, explains; and yet, with rare inconsistency, whilst he admits the truth of my propositions, he occupies an hour and forty minutes of the valuable time of this Society, engrossed with a vital and all-important question, upon which so much depends, and in which our profession is as much upon its trial as are the lives of those women he admits to be sacrificed; he occupies, I say, this Society for an hour and forty minutes, whilst confirming my position, in trying to detect flaws in my arguments, in dwelling upon accidental slips of the pen, in the transcription of my figures, and in magnifying them into grave errors of calculation. But, excuse me, sir, I am imitating his bad example, and forestalling statements to come.

But, it has been attempted by Dr. McClinton, Dr. Athill, &c., with more ingenuity than candour, holding me to the strict letter of my proposition, that the mortality was in direct proportion to the number of parturients in a given space, to prove that I had asserted that that general statement applied *ever* and *always* to the *very time* at which that crowding was observed. I did not, however, make any such statement. On the contrary, the whole tenor of my reasoning goes to prove the reverse. I dwelt especially on the capricious nature of this zymotic disease, and referred to the statistics of the lying-in hospital as showing this peculiarity in its endemic hauntings. But I went a great deal farther. I showed in distinct, unmistakable language what was intended in this proposition. Yet, strange to say, every gentleman who has attacked this Redan proposition has found it convenient to ignore these facts.

Page 293 of my paper states:—"If you will cast your eye along the Dublin Lying-in Hospital table there furnished, it will give you, at a glance, the longest duration of these endemic hauntings to which the hospital has been liable since its foundation. Observe where there are two figures in place of three, you will thus arrive at a rough result." Now, mark me, gentlemen. "From 1761 to '65 was one of these; again from 1767 to '70, and from 1772 to '74. From this year down to 1800 we meet only an occasional unhealthy year, but it remains at two figures until 1804, and so on, with only an occasional unhealthy year until 1818, the most crowded state the hospital ever was in; in that year there were 3,539 deliveries. For three years the mortality then arose to 1 in 44; in 1826 it arose again, and continued for the next four years at 1 in 50." If language means anything, it will be evident from this, that I state that the mortality arose and continued as the result of the previous crowding. It will be perceived this convincing evidence of the truth of the sixth proposition has been inserted in italics, to prevent its again escaping the notice of my critics. Sir, I feel called upon to do this, and to dwell thus on this quotation, because, although I pointed out this passage and these figures of Dr. Labatt's mastership to Dr. Athill on the first night of discussion, as refuting his assertion and confirming my proposition in the most conclusive manner, other gentlemen have followed his bad example, and ignored this passage in treating of this subject.

Had my commentators taken the trouble of examining the history of the hospital, they would have found, however, as above alluded to, an especial explanation of the delay in the outburst of the disease until the year 1817, although the numbers had been increasing from 1815 to 1818 by nearly 1,000 deliveries; it was this. In the year 1815 the crowding was checked by the purchase of what had been the hospital for the blind, which was then added to the institution. This lessened the crowding. It partially isolated, by separating the patients, and thus the outburst of the disease was delayed for two years. Not only this, but the death-rate absolutely fell

from 1 in 100, where it stood in 1814, to 1 in 180 in 1815, and to 1 in 182 in 1816.

What could be more convincing, then, than this period of 1818 in confirming the relations between crowding and death-rate insisted upon by me?

Drs. McClinton, Athill, and their friends oblige me to analyse in detail the saliently marked periods which show the mere relation between increase, diminution, and death rates in the hospital, as they have done, a not uncommon thing with young philosophers, they have confounded cause and effect. They say:—"It so happens that during the year 1800, '1, '2, '3, '4, being the five years that immediately preceded those whose statistics I have just quoted, the annual deliveries averaged 500 less than the succeeding ones, being 8,900, yet the mortality was more than double, being 1 in 66." Now, let me ask, why did the deliveries average 500 less, and why did the mortality increase *pari passu* with this lessening? Simply because the overcrowding of the hospitals in the four preceding years, namely, 1796, '97, '98, '99, had engendered the disease, 6,474 patients having been delivered in it in that time, and their admission in 1797 having amounted to 1712. Dr. Evory, whose astute mind and experience pointed out the cause of the increased mortality, consequently limited his admissions, and in 1799, when the disease showed itself, he reduced his deliveries to 1,537, and again in 1800 to 1,337; but it was too late. The disease had found its habitat in the hospital, and continued its havoc for four years.

The indiscreet master who succeeded, Dr. Kelly, would not take the example of his predecessor, but allowed the patients to crowd into hospital, in increased numbers, until the year 1803, when the patients numbered 2,028, and the death-rate reached 1 in 46. Now, as nearly as possible the same thing had occurred in the last three years of Dr. Joseph Clarke's mastership. The deliveries had amounted to 4,990; the highest average up to that time, and in his last year, 1793, they reached 1,757. In that year the death-rate rose from 1 in 163 to 1 in 92, and the disease having found its habitat, the death-rate got to 1 in 77 the next year.

Dr. Evory, however, lowered his deliveries to 1,543 in 1794—in 1795 to 1,503, and in the latter year the death-rate only amounted to 1 in 214. The same thing exactly takes place with Dr. Hopkins. From the year 1806 to 1809 the deliveries increase from 2,220 annually to 2,889. The death-rate rises from 1 in 205, where it stood in 1803, to 1 in 98 in 1810; and although the deliveries are reduced by nearly 400, or to 2,484 in 1813, the death-rate reaches 1 in 40, because the disease has now found its habitat.

A fatal blindness seems, however, to follow our ministrations from the earliest periods of the management of this institution. The diminution of deliveries is attended with its consequences more speedily on this occasion than usual. The death-rate is reduced to 1 in 100. Dr. Labatt's mastership commences in 1815; patients crowd into the hospital again; the admissions reach 3,276 in 1816, and the death-rate stands at 1 in 182. But despite the relief afforded for a time by the increased accommodation afforded by the addition of the blind house, the fatal result, although delayed, is certain. The next year the deliveries amounted to 3,473, the death-rate rises, of course, to 108. Still the experience of former masters is disregarded, the deliveries are permitted to increase to 3,539, and the death-rate increases to 1 in 63; and although when too late, the deliveries are diminished next year to 3,197, the death-rate rises still higher to 1 in 33, the disease having now found its habitat, and retains it for another year, although the deliveries were reduced by 600, or to 2,458.

By a strange infatuation the deliveries were again allowed to increase to 2,849 in 1821, and to 2,675 in 1822; and though lowered in 1823 to 2,584, the death-rate rose to 1 in 44. In 1824 the deliveries were still further lowered to 2,446; the

death-rates were reduced to 1 in 122. In 1825 the deliveries increase to 2,746, the death-rate increases to 1 in 105. The habitat is established, and although the deliveries in 1826 are lessened to 2,440, the death-rate rises to 1 in 30.

In this year I first became acquainted with this fell disease, as a pupil of the Lying-in Hospital, and when I call to mind the deep impression made upon my mind by witnessing the death of eighty women in one year by this disease, and of 191 for the four years that I attended as a pupil, most of whom had entered the institution in youth and health, buoyed with the hope of a speedy restoration to their homes and families, it is not to be wondered at that forty years has failed to efface it.

But, sir, painful as it is, I must persist in the cruel task I have set myself. The habitat was now thoroughly formed. The poison miasm pervaded the hospital thoroughly. Dr. Collins's mastership commenced in 1827, and he adopted every precaution that the resources of our art could devise to combat it. The deliveries, however, were increased by upwards of 100 that year, amounting to 2,550; the mortality was 1 in 77. In the next year (1828) the deliveries were increased to 2,856; the death-rate rose to 1 in 66; and although the deliveries were reduced in 1829 to 2,141, yet the habitat was there, and the death-rate was 1 in 63.

The reduction of deliveries, which Dr. Collins never after this allowed to amount so high as those of the next year, 2,288, told, and with the other means so minutely detailed in Dr. Collins's work, diminished his death-rate to 1 in 190, and it did not rise beyond 1 in 178 for the next three years.

It may be better to dwell briefly at this period of the history of the hospital; as, with the termination of Dr. Collins's mastership, an entirely new phase in its history is developed. The conclusions to be drawn from what has preceded are, that on every occasion when the hospital was crowded, sooner or later metria showed itself. Secondly, when this occurred, its habitat became established, and it continued for a longer or shorter time, notwithstanding every means that could be adopted: and although a reduction in the number of deliveries had an effect in ultimately improving the healthiness of the hospital, even these measures repeatedly failed in abating the evil immediately, when once the habitat of metria was thoroughly established. Let us now recapitulate the third and fourth propositions set forth in my prayer, namely: third, that the generation and absorption of the metria poison or contagion is in a direct proportion to the number of parturient females cohabiting at their parturient period, or who breathe the same atmosphere at the time of their delivery; and the fourth:—that in lying-in hospitals, where large numbers of patients are delivered under the same roof, this disease finds its habitat, appearing and reappearing at uncertain intervals.

If ever propositions were established by multiplied facts, and confirmed by prolonged experience, I submit these proportions have been so by the preceding analysis. But, as the object of this paper is, not merely to obtain a barren victory by the ingenious manipulation of a number of figures, but to carry conviction to the minds of the profession, and through them, to the public, let us reason a little more closely upon the laws which appear to be derived from a study of the history of the metria hauntings in the hospital.—Firstly, that markedly as these attacks occur in direct proportion to the number of parturient females cohabiting at their parturient period, yet the contagion is cumulative, or growing in its contagious power, requiring a longer or shorter time to arrive at its full intensity or saturation. This law accounts for the interval of time observed to elapse, before the outbursts of the disease, and after the cause which experience has proved to be the most invariable, if not the only known cause of its development, after it has been generated.—I allude to crowding.

Again, although it is true that the spread of the disease is in proportion to the number, it is a mistake to suppose that this

crowding requires a large number of patients to produce it. We have seen, by the diminution of the mortality in the Waterford Cottage Hospital, on changing the number of beds from six to two in the wards, that it was not the presence of a large number, but the crowding of what we might say a comparatively small number, that sustained the mortality at its higher rate. The same fact is proved by the large mortality observed to occur in the London Hospitals, containing thirty and fifty beds, and in the other hospitals enumerated in Dr. Churchill's table.

Now, ingeniously and pertinaciously as my critics have endeavoured to keep this latter law in the shade, and pervert it as an argument against my proposition, neither their facts nor their logic will hold for one moment on this subject. No incompatibility whatever exists between the latter law and my general proposition. I affirm that a zymotic disease is conveyed by the absorption of poisonous contagion. I lay down a general proposition, that the generation of this poison will be in the direct proportion of the number of patients subject to the conditions on which it is generated, and breathing the atmosphere charged with it. I require that, to lessen or prevent its generation and spread, the number generating and exposed to the spread of the poison should be reduced to a minimum. That minimum might be one, but, should not object to two, at least, until the success had been sufficiently tested. Need I remind my illogical young critics, that the major comprehends the minor; and that if more than one patient inhabiting a ward increases the liability to generating the poison, and the certainty of its spread and extension, that *a priori* the "generation and extension must be in exact proportion to the number of parturients exposed to it, and breathing the same atmosphere." So far, then, from the mortality in the medium-sized or small hospitals, hunted up by my critics, and a fearful array it was, but especially the mortality in the York-road, the Glasgow, the Edinburgh, and Dr. Beatty's hospitals; I say, so far from their mortality making against my proposition, properly understood, they all confirm and strengthen them, because they present the conditions I object to in a more marked degree; possessing all the objections and vices, with none of the advantages of the great lying-in hospitals.

(To be continued.)

CALABAR BEAN IN TRISMUS NEONATORUM.

Dr. Alois Monti, of the St. Ann's Childs Hospital, reports three cases out of five cured by this remedy. He prefers subcutaneous injections, as he thinks the internal use uncertain. He repeats these injections every ten or fifteen minutes until the spasms cease; then intermits them even for several hours until the cramps return again. For new-born children he uses one-tenth grain of the extract per dose, and goes up to one-third, one half, or a whole grain a day. Older children can commence with one-third grain per dose. For internal use, from one to four grains a day may be given.—*Jahrb. für Kinderheilk.*

INFLUENCE OF CLIMATE ON VENEREAL DISEASES.

The evolution of syphilis, according to M. Lagneau, would be less rapid in cold than in warm countries, at Christiana than in France, in France than in the tropical regions. Gonorrhoea, very common in the United States, less so in China, would scarcely manifest itself amongst the natives of Algeria and the Levant, except those in contact with Europeans. Syphilitic maladies should be cured less readily in cold than in warm countries, and easily with the negroes. When two races come in contact in the same country, syphilis falls most severely on that which previously had been least subject to it. Individuals who contract syphilis in any country would find its effects to amend in a warmer climate, and to be aggravated in a colder one. Syphilis, though universally diffused, would seem unable to establish itself permanently in Iceland, situated almost under the polar circle. According to Livingstone, it would be spontaneously cured in the interior of Southern Africa.—*Jour. de Med. et de Chir. Prat.*

SCOTLAND.

THE TESTIMONIAL NUISANCE.

EDINBURGH, August 24.

How it is in other parts of the world we know not; but here, whenever any of our University Chairs become vacant, every would-be candidate immediately sends forth by every post copies of his last work, or a statement of what he has done and intends to do in regard to that particular branch of his Profession, to all the many hundreds of his brethren in every quarter of the globe, whose opinion he thinks may be of service in helping him to gain his end. Having thus cast his bread upon the waters, he waits, with what equanimity he may, until the returning post brings the hoped-for replies, which are immediately printed and again circulated to the patrons of the vacant Chair first; to all who can by any means influence these, second; and, lastly, to the general public; so that, failing THE CHAIR, the candidate may at least attain a certain amount of *Kudos*—some never hope for more than the latter; let us hope they gain it. Such *Kudos* must be a poor return for all the trouble, not to speak of expense. Now this seems to us to be a most absurd mode of procedure; we can understand and appreciate the value of a competitive examination, or the exercise of high-handed interest, as in our Crown appointments; but to measure the worth of a candidate by the number of testimonials he has the impudence to beg, or the luck to secure, or by the amount of facial contortion required to pronounce the names of their authors, seems to us of all absurdities the most absurd. It would be better by far to weigh each volume, or to measure its length and breadth, and let the heaviest book and the largest sheets carry the day. Material bulk is *presence* of a certain kind, and, though occasionally inconvenient, is undoubtedly a thing of weight. But names, however jaw-breaking they may be, are only valuable in proportion to the dignity and trustworthiness of those who own them (we were about to say); but though that is true, it is not all the truth, and must be qualified in regard to testimonials; because a man may be a most distinguished surgeon, and yet not capable of duly appreciating shades of difference in candidates for a Chair of Practice of Physic; or, being a contemporary of B., and having a very proper admiration for his talents and acquirements, he may ignore those of A., before whose time the whole subject of their mutual investigation was a chaos dark as Erebus itself. A.'s discoveries to him are only part of the inheritance derived from the mighty men of old; B.'s seem to him advances; but he forgets that A. is that man who has rendered B.'s advances possible. In a matter such as that to which we refer, names, to be of value, must be those of masters of some standing in that particular branch to which the Chair refers; and if to that special qualification be added a personal knowledge of the candidate, then such testimony ought to outweigh any amount of comparatively less valuable evidence. We have been led into these remarks by the simultaneous appearance on our table of the testimonials of the two candidates for our Chair of Pathology, whom we formerly pointed out as being the most distinguished. Both of these are very well known to the Profession here, because their whole life and work have been before them, and yet how widely do their testimonials vary! Forty-one of the most distinguished professors, teachers, and medical

practitioners in Edinburgh concur in their opinion that Dr. Sanders is preeminently qualified, by his attainments and success in pathological investigations, for the vacant Chair of Pathology, while only five of our Edinburgh medical practitioners venture to say a word for Dr. Stewart, and of these three have only recorded as it were second votes for him, having given their first and best unreservedly for his opponent. Bad as the system of testimonialising is, such an overwhelming amount of evidence in favour of one from those among whom both have so long lived and worked, cannot but have an important influence upon the curators, to whom most of the testimonial-givers are personally known, and who have, at all events, the means at hand of correctly estimating the value of the testimonials given, and who unquestionably know very well whether the five outweigh the forty-one, or even a tithe of them, in professional repute, in scientific name, or in mere trustworthiness.

Dr. Stewart, however, has studied abroad, and has very properly kept up an acquaintance with his old fellow-students, whose names, now rising to distinction, crowd his pages with well-deserved encomiums of their old companion. We honour them for their leal true-heartedness, and we congratulate Dr. Stewart upon their personal esteem. But no one would for one instant place in comparison with their testimonials those received by Dr. Sanders from such veterans in pathology, such household names in European science, as Virchow, Broca, Bouilland, Rokitansky, Wedl, and Donders. It is an awful nuisance to candidates and their friends, and it must be equally so to the patrons of a Chair, this system of testimonialising. We are strongly of opinion that it ought to be forbidden, that the names of intending candidates being sent in, the patrons ought to select one or more of the most distinguished Professors in the department vacant, and, referring the conflicting claims to them, abide by their decision. Let us see how this would affect our present candidates for the Chair of Pathology. We suppose that no one will deny the claims of Virchow to be considered the foremost pathologist in Europe. In the present instance he has acted unconsciously as referee, he has given a testimonial to both candidates, and we think the friends of both ought to be well content to abide by his decision. Virchow acknowledges Dr. Stewart to have been one of his most distinguished students, and regards him as well qualified to do honour to the Edinburgh University as the Professor of Pathology; but he confesses that the pathological researches of Dr. Sanders have not only confirmed, but have at times been in advance of his own when treating of the same subjects. If it be an honour to Edinburgh to have as its Professor of Pathology a distinguished student of Europe's most distinguished Pathologist, surely it must be a still greater honour to secure the services of one by whom even Virchow's knowledge has been increased—has received at times "*cine Bereichenung*." We congratulate Edinburgh on its candidates for the Chair of Pathology, and we also congratulate the curators on the comparative lightness of their task, which, to satisfy the Profession, can have but one termination.

THE CHAIR OF CLINICAL SURGERY.

THE Queen has been pleased to approve the appointment of Mr. Joseph Lister to be Regius Professor of Clinical Surgery in the University of Edinburgh.

UNIVERSITY OF EDINBURGH.

HER Majesty has been pleased, by Order in Council, to approve of reports by the University Court of the University of Edinburgh, recommending that Professor Syme and Professor Henderson should be permitted to retire from their respective Professorships on retiring allowances.

SCOTTISH REGISTRAR-GENERAL'S RETURN.

THE Registrar-General for Scotland reports that only 29,472 births were registered in Scotland in the second quarter of the year 1868, being in the annual proportion of 3.67 per cent. of the estimated population. The average of the quarter in the previous ten years was 3.80 per cent. The birth-rate in the town districts in the quarter was 4.05 per cent.; in the rural districts 3.25 per cent. The births registered in Scotland averaged 333 a day in April, 316 in May, 323 in June. So low a birth-rate was not registered in the Spring quarter of any one of the preceding ten years. Unhappily, on the other hand, the death-rate for the quarter had never been so high in the ten years. 19,499 deaths were registered in Scotland, being at the annual rate of 2.42 per cent., the average being only 2.22 per cent. The ratio in the town districts was 2.90 per cent., in the rural districts 1.82 per cent. It reached 3.31 per cent. in Edinburgh, 3.36 in Greenock, 3.70 in Glasgow. On an average 222 persons died daily in April in Scotland, 207 in May, 212 in June. The marriages, 5,596, were in the annual proportion of 69 in ten thousand persons, the ten years' average being 70, but in 1866 there were as many as 76. The marriage-rate was 0.82 per cent. in the town districts, 0.54 in the rural districts. The high mortality of the quarter was apparently caused by the unusual prevalence and biting severity of the northerly winds, which, during May and June, blew with a constancy rarely witnessed in Scotland, and a keenness such that, even on the 15th, 16th, and 17th of June, the whole of the high ranges of hills were covered with snow. The consequence was that, instead of June being one of the six healthiest months, as it usually is, its mortality was as high as January, one of the most fatal months. That the increased mortality was mainly due to the biting severity of these northerly winds was demonstrated by the fact that the towns and parishes which were sheltered from these winds had a mortality below their average, while those exposed to them, as Glasgow, Paisley, Greenock, and Edinburgh, had their mortality greatly increased. The cold weather accompanying these winds did not merely increase the prevalence and fatality of the diseases of the respiratory organs, but of all diseases, even those usually termed epidemic—both the epidemics of adults and of children. It had also a particularly baneful influence on those advanced in life, so that in many parishes all the most aged inhabitants were cut off. Among the notes appended to their returns by the local registrars is one from the registrar at Coull, in Aberdeenshire, who remarks:—"A new disorder is very common at present. The symptoms are sore-throat, acute headache, and an eruption like that which accompanies scarlatina, but the spots are above and not under the skin." The Registrar-General observes that this is probably an outbreak of the disease termed "Dengue," an eruptive fever common in the West Indies, but which has at rare intervals appeared as a local epidemic in this country.

IODINE AND ACONITE IN PERIODONTITIS.

Professor Abbott writes:—"The best remedy, and the one that works the most conveniently for periodontitis, I have ever used, is a mixture of equal parts of officinal tincture of iodine and tincture of aconite root applied to the gum around the roots of the tooth with a camel's-hair brush, or a portion of cotton-wool at the end of a stick. I have been using it for a year, and have not found it fail. I apply it, in the early stages of the inflammation, once in the twenty-four hours, and in very severe cases twice.—*Boston Journal*."

NITRATE OF SILVER IN RHEUMATIC PARAPLEGIA.

Dr. Caradec, of Brest, reports a case occurring in a hump-backed person, but caused by living in a damp dwelling. There were pains in the back, arms, loins and legs; intense hyperæsthesia of the skin of the legs, and twitchings of the muscles, followed by paralysis of the limbs and sphincters. The nutrition and temperature remained normal. The pains were followed by total anaesthesia as high as the upper fourth of the thigh, and the paralysis became complete. After this state had lasted a year, he was put under the use of nitrate of silver, from one to eight centigrammes per day. An evident gain in sensation and motion was noted in three weeks, and an almost perfect recovery in three months. The patient remained well for five years. The good effects of the nitrate of silver are regarded as undoubted, and the remedy is confidently recommended for similar cases.—*Gazette Hebdom.*

A NEW METHOD OF TREATING THE PEDICLE IN OVIARTOMY.

Dr. Julius F. Miner, in the *Buffalo Medical and Surgical Journal* (June, 1869), advances what will seem to most surgeons to be a very startling proposition—namely, that in many cases, ligatures, clamps, or cautery, may be dispensed with in the operation for ovariectomy, and the pedicle returned without danger. His opinion is formed upon a case in which he removed an enormous ovarian tumour by the following operation:—

"The tumour was multilocular, very large, weighing, as near as could be ascertained, between seventy-five and one hundred pounds. It was attached throughout its entire circumference to the omentum, intestines, walls of the abdomen, and all other parts with which it came in contact. These attachments were not so firm but that they could be broken up, and with great care the tumour was separated from the surrounding parts until the pedicle was reached. The process of enucleation had been carried on so extensively and successfully that encouragement was afforded for continued trial. The pedicle was large, and extended over a wide surface, but by patient and gentle effort it was separated from its entire attachment to the tumour, and the immense growth removed without the ligation of a single vessel. The terminal branches of the vessels of the pedicle gave out no more blood than issued from the vessels of the attachment elsewhere, and there appeared no more occasion for ligature here than elsewhere. All hæmorrhage soon ceased, and the incision was closed by interrupted suture." Dr. Miner adds: "The ovarian tumour is generally composed of a firm, dense, fibrous cyst, containing fluid of very varied colour and composition. It may, and it may not, have a solid portion, but usually it does have more or less of a body, the remnant of an enlarged or degenerated gland. Upon the surface of this smooth dense cyst are spread out the vascular, fibrous, cellular, and other tissues which compose the pedicle, but only the terminal branches of the vessels enter this cyst; the vessels may be quite large at their origin, but soon they are numerous divided and enter the cyst, if at all, of capillary size. The attachment of the pedicle to the cyst is more easily broken than any one would mistrust who has not attempted its separation in the manner described, and I am confident that the same efforts which are made to break up adhesions to the peritoneum, omentum, and other parts, if extended to the pedicle, will, many times, be equally successful."

In cases where this method of enucleation without ligature may be found impracticable, Dr. Miner advises a modification of the principle of acupressure—"that is, a needle with ligature attached, passed transversely through the pedicle, weaving it in such manner as to make pressure upon the vessels sufficient to arrest the circulation. Where this method can be made effectual, it approaches very near in point of favour to enucleation without ligature, since the needle can doubtless be very early removed and the parts beyond the point of its introduction need not be strangulated or the vitality destroyed so as to produce sloughing."

The plan of enucleation thus suggested is eminently worthy of trial by other surgeons, and should subsequent experience confirm its practicability, ovariectomy will be shorn of some of its most hazardous features. The well-known variability in vascularity of the pedicle of ovarian tumours, however, renders great caution advisable in determining the cases wherein this method should be attempted.

WEDNESDAY, AUGUST 25, 1869.

LOCAL MISMANAGEMENT.

SOME individuals are so unfortunately constituted that they crave for notoriety, and, rather than not be talked about, will make themselves ridiculous or despicable. This state of mind appears to prevail very strongly in certain localities, of which we hear occasionally.

In the North-Western district of the great Metropolis is an extensive parish, containing a population of little less than a quarter of a million souls—a large proportion poor—which may be said to have been given up by the Legislature to the great railway interests, and by the land-owners to speculating builders, peculiarly afflicted in this manner.

The Board of local magnates who administered the affairs of this parish some three years since contrived to make themselves so unenviably notorious that no person of sense or position would consent to be associated with them; but the disgraceful neglect and ill-treatment of the poor at length compelled the more respectable inhabitants to bestir themselves. The divisions amongst the mis-named Guardians, who, having quarrelled with the magistrates, the coroner, and the Poor-law authorities, were quarrelling amongst themselves and roundly abusing each other, and the passing of an Act of Parliament in 1867, constituting magistrates residing in the parish *ex-officio* members of the Board of Guardians, facilitated their proceeding, and enabled them to remedy some of the most flagrant abuses.

The manifold evils of inefficient management were everywhere apparent—many were redressed—the deserving poor received more adequate relief—the workhouse was made more comfortable for the aged and infirm, and other improvements introduced, the additional cost of which was officially reported as more than counterbalanced by the withdrawal of grants to the undeserving and the prevention of waste and peculation.

Finding that the sick poor could not be suitably pro-

vided for in the workhouse; that the foul atmosphere of the existing infirmary—to which the death of one, and the serious illness of another medical officer was attributed—retarded the recovery of the patients; these gentlemen, acting under the directions of the Poor-law Board, entered into a contract for the erection of an infirmary for 524 beds, on an open space in the parish well adapted for the purpose, the cost of which it is estimated would be defrayed by a rate of three farthings in the pound.

Receiving notice that the children must be removed from the schools in which they had been placed at a cost of 10s. 6d. per head weekly, they set about erecting schools for 700 children, at a cost of £37,500, the whole of which, with the interest, would be repaid in a few years by the saving effected in their maintenance—estimated at about half the amount recently paid.

Whether the Guardians acted upon the most economical principles we cannot decide; but as their opponents cast no imputation upon their motives, and they are proved to have acted in other respects with discretion, and in these matters with the sanction (if not under the directions) of the Poor-law Board, we must give them credit for prudence in these also. But these changes involve immediate expense; new buildings must be paid for—the rates for a time, at least, must be increased. Higher rates signify reduced rentals, and involve reduction in the price of newly-built houses. Certain busybodies were therefore induced to establish a Ratepayers' Association, to ensure the dismissal of extravagant Guardians, and the election of men pledged to economy, or, rather, to a reduction of the rates. The Association succeeded in returning a majority of their candidates, amongst whom we regret to see the names of two members of our Profession, at the last election, who set about their work by quarrelling with the *ex-officio* Guardians and the Poor-law Board as to the hour of meeting.

Believing the Master (who is acknowledged to be an intelligent and exemplary officer) to be opposed to their proceedings, the new Guardians—now distinguished as the Numerical Majority, in contradistinction to their opponents, who are styled the Intelligent Minority—suspended him; but the Poor-law Board, after due investigation, ordered him to be reinstated, on the ground that there appeared to be no foundation for the charge; the majority, while complying with the letter of the order, decreed a fresh suspension, without any charge being even intimated, upon which the Poor-law Board issued an imperative order for the Master to take charge of the workhouse, and deprived the Guardians of the power of suspending any official during the remainder of their year of office.

But our business is with the infirmary and its inmates, rather than with the general management; unfortunately, the sick poor are the first sufferers, the strong and healthy can remove themselves from, or bear up against, influences which crush the weak and delicate, and medical officers are necessarily made to appear prime movers in cases of suffering and cruelty, when really they have borne but a very subordinate part.

In this case, a poor woman having died, an inquest was held by the Coroner, when it was stated that the Guardians, being desirous of clearing the infirmary in order to prove it is sufficient for the purpose, and that the new building is unnecessary, had directed the medical officer *pro tem.* to remove as many of the inmates as possible, and that such removal had been the cause of death in this as

in other cases. That the patient had died shortly after removal from the infirmary was clear; but the conduct of the authorities in the matter being now the subject of an official enquiry by order of the Poor-law Board, we refrain from any expression of opinion as to the degree of responsibility attaching to the medical officer.

While this case was still pending, another, equally painful in its details, came before the public. An unfortunate man, deprived by sickness of the ability to provide for his family, had been assisted by a grant of five shillings weekly, in addition to which his wife earned some ten shillings by her exertions; the new Guardians withdrew the grant, and directed him to sell his furniture and come into the house with his family; to this the wife naturally objected, that by so doing she would lose her home and the means of earning her livelihood; that she would thus become a permanent inmate of the workhouse with her children; and that a little assistance—even a shilling or eightpence per week—would enable her to keep them out of it. The Committee were firm; they would only give them indoor relief; the poor man died, and at a coroner's inquest it was stated that his death had been accelerated by the anxiety thus occasioned.

When we find Boards of Guardians thus blind to the real interests of the parish, and unmindful of the wants of the poor, whose guardians they are supposed to be, what are medical men to do?

We have gone fully into the history of this case, as it may be considered to some extent typical, although, we trust, an extreme one.

If such things can occur in the Metropolis of England, in the borough of Marylebone, for years distinguished by its claims to political influence and opposition to centralization, what may not happen in small towns and out-of-the-way parishes? and what security have medical Poor-law officers that they will not be crushed by the misconduct of petty tyrants, clothed with a little brief authority, who play such tricks, free from the supervision of the press, and, to a great extent, from the control of public opinion?

THE THUNDER OF TUAM.

FOLLOWING at a respectful interval the glorious footsteps of the great Finlen, the town commissioners and clerical echoes of Tuam have vindicated the disputed right of public meeting, and in farcical solemnity have asserted most decisively the right of the free Briton to talk nonsense and make himself ridiculous. Disdaining the hacknied subjects of the Irish Church or Tenant Right, the little clique have expended their energies on so small a subject as the local doctor, and in the fervidness of their rhetoric have absolutely frothed again. We published some weeks since a letter from Dr. Kinkead on the subject of Prostitution, a contribution to the discussion which had lately occupied a part of our columns. Dealing with the matter in the most general way, Dr. Kinkead repeated the statement, which all the world knows to be a truism, that a certain class of women "standing behind the counters of shops by day act the harlot by night." This remark was quite as applicable to Hong Kong as to Tuam, yet a knot of little great men, in company with and possibly at the dictation of local clerics, seized the occasion for a display of virtuous indignation against the medical man, whom, for reasons

known to themselves and their instructors, they seem to have been desirous of exterminating. The vaporous exhalations of the speakers are too precious for obscurity, and we therefore append extracts:—

Mr. Shine proposed the following resolution:—

"Resolved—That we, the merchants, traders, and shopkeepers of Tuam, have learned with supreme disgust and burning indignation that there has been found in our midst a man capable of publishing to the world the palpable untruths and reckless scandals contained in a certain letter in the MEDICAL PRESS AND CIRCULAR of July 7th, signed R. J. Kinkead, and that we repel and repudiate with scorn the vile charge insinuated against a class to which all who are nearest and dearest to us on earth belong, and so insultingly alluded to as '*standing behind the counters of shops by day while acting the harlot by night.*'"

"We, moreover, protest against the tenor of his letter as a libel on the national character, which, we are proud to say, has admittedly held a first place amongst the nations of the earth for the purity of its daughters."

Mr. Shine said:—"Mr. chairman and fellow-townsmen, in proposing this resolution for your adoption, I must observe that the extract from Dr. Kinkead's letter which I have just read contains, as you all know, a foul and dastardly imputation on those beings who are nearest and dearest to us all—our wives, our children, our sisters, and friends—in fact, on all those whom we love best—for I may say they all stand behind counters. (Groans.) I tell the foul-mouthed author of that base and bitter libel that they whom he has aspersed are not a whit his inferiors. If Dr. Kinkead looked above him and directed his inquiring but evidently prejudiced gaze to those classes whom he endeavours with rather doubtful success to become identified with in the social scale, he would perhaps find actors fitting his congenial description. If he were present, I would hurl back in his teeth the base aspersion which he has aimed at the honourable daughters of industry."

Rev. James M'Gee, C.A., said:—"The meeting has for its object the denunciation of as vile statements as could well emanate from the pen of any man, and which you conceive to bear slanderously upon yourselves; and I must say that unless you did so resent this gratuitous and gross insult, you would richly deserve the treatment you have received. I may be allowed to premise that to the mere theories of Dr. Kinkead, or any other man, we have nothing to say, so long as they do not bear injuriously upon ourselves, or affect the interests of morality and religion. But what we complain of is, that a man living in our midst should, with the confidence of everyday life experience, publish to the world, as applicable to all times and all places (and of course that in which he resides, and from which he is supposed to derive his experience), a state of things which you and I know to be as opposed to truth as it is slanderous upon ourselves." (Cheers.)

It is obviously impossible to believe that the foregoing rhodomontade expressed any real feeling of anger, or that the speakers truly considered that they or their town were specially touched by Dr. Kinkead's remark. We should think even less of them than we do if we credited their possession of that degree of stupidity.

We are relieved, however, of any doubt by the observation of the persons who took part in the movement. Three out of five of the speakers were local ecclesiastics, and the speech of the last was an elaborate glorification of the religious system which provided such earnest and honest champions against cavillers of an opposite creed.

The whole affair bears the appearance of an attempt at religious persecution, all the more despicable because it is inaugurated under a false pretence. Dr. Kinkead may

rest satisfied with the assurance that if contempt or discredit be applicable to any parties to the controversy, it is not to the temperate exponent of the strict truth, but to those who resort to a despicable subterfuge to crush an obnoxious person. The entire affair is no less a caricature of the right of public meeting than it is of real honest indignation.

Notes on Current Topics.

Trinity College, Dublin.

NOTICE has been given that, after the year 1869, candidates for the degree of Master in Surgery will be required to produce certificates of practical instruction in ophthalmic surgery, of at least three months' duration.

Masters in Surgery are entitled to be registered for the Parliamentary franchise without payment.

Vaccination in India.

THE *Pioneer* observes, that notwithstanding the vigorous efforts of the Vaccine Department, the inhabitants of Rajpootana do not seem to have much faith in the practice of vaccination. In Tonk, however, and some of the Marwar villages, the vaccinator is welcomed and even sent for. In the hill villages around Aboo the people submit to the vaccinator readily enough; but everywhere else in Rajpootana the staff of vaccinators meet with very indifferent success.

Ammonia as an Antidote for Snake Poison.

THE *Indian Medical Gazette* contains a long account of further experiments by Dr. Fayrer on the influence of snake poison. The remedy tested this time was injection of ammonia into the circulation, as recommended by Professor Halford of Melbourne. But Professor Halford's experience seems doomed to be contradicted by Indian experiment in every instance. The ammonia, thus exhibited, appeared rather to expedite death than to prevent it. The contradiction between the results of Australian and Indian experiments is becoming almost as inexplicable as the nature of snake poison itself.—*Indian Examiner*.

The Cattle Plague.

In the district of Frankfort-on-the-Oder the cattle plague broke out during the last days of July. Official inquiries have proved that it was introduced by a herd of cattle which were bought at the market of Muhlhausen in East Prussia. It has spread to four or five villages. As, however, the strictest measures have been adopted to prevent the infection being carried further, and the villages in question have been closed by a military cordon to all trade in cattle and fodder, it is hoped that the plague will soon be extinguished.

The Indian Pharmacopœia.

THE Pharmacopœia of India Committee have issued a volume embracing the results of their labours. The British Pharmacopœia issued by the Medical Council of England in 1867 having introduced many important changes in the nomenclature and composition of many important preparations, the Secretary of State considered it advisable (says

the *Englishman*) to remodel the Bengal Pharmacopœia of 1844, and to sanction the publication of an Indian Pharmacopœia based on that for England. This work was entrusted to a committee composed of Sir J. Ranald Martin, president, Sir William O'Shaughnessy Brooke, Alexander Gibson, Daniel Hanbury, Drs. Thomas Thomson, John Forbes Watson, Robert Wight, and Edward John Waring. Dr. Waring acted also as editor of the Pharmacopœia. The work produced by the labours of these gentlemen is most valuable, embracing as it does the labours of numbers of Indian officers, and the results of the researches of some of the best native medical men.

Health of Dublin.

IN the Dublin Registration District, the births registered during the week ending August 14th amounted to 134. The average number in the corresponding week of the years 1864 to '68 inclusive, was 158. The deaths registered during the week were 123. The average number in the corresponding week of the previous five years was 124. Fever caused 6 deaths, 3 of which were from typhus, and 3 from enteric or typhoid fever. Seven deaths resulted from measles. Five deaths from scarlatina and 1 from diphtheria, were registered. Erysipelas proved fatal in 2 instances. Six deaths were ascribed to diarrhoea, and 1 to infantile cholera. Six deaths were caused by bronchitis, and 3 by inflammation of the lungs. Convulsions carried off 12 children. Four deaths were attributed to apoplexy, 2 to paralysis, and 5 to cephalitis or inflammation of the brain. Fifteen deaths resulted from phthisis or pulmonary consumption. Two deaths were caused by heart disease, and 1 by aneurism. Five accidental deaths were registered during the week, viz., 1 by injuries to spine; 1 by drowning; 2 by inhalation of poisonous gas; and 1 by "accidental hæmorrhage."

The Fever Haunts of India.

DR. SMITH'S brief report on the fevers of Bengal, in reply to a memorial on the subject, is extremely emphatic. Of one village—the worst—he says:—

"Here is a concentration of everything that is insanitary. Dr. Thompson and I, after being in the village for about ten minutes, both began to suffer from headache, and to experience general discomfort. Near the centre of the village is a tree upon which we observed numerous vultures' nests; the birds themselves were looking down unscared upon the festering scene below, which is literally a lair only fit for the wildest beasts of prey."

The extent of the evil is so alarming that complete desolation of the district must be the result in another ten years, if it is not checked. Sixty or seventy per cent. of the rural population, and five-sixths of the children under eight years of age, are believed by Dr. Smith to be suffering from enlarged spleen. "An atmosphere of silent despair seems to hang over the worst villages; and no wonder indeed, for everything is rotting the air, the ground, the vital organs of the people. We thus see humanity reduced to one of its most abject conditions; uncouth, cadaverous men and women, surrounded by pitifully diseased children, moving silently about in a stronghold of malaria, which they call their village home, where every draught of water and every breath of air inhaled is poison." Dr. Smith enumerates eleven villages which have lost upwards of sixty per cent. of their inhabitants, and the figures are probably

not much exaggerated, though they may not be exactly correct; and though the same rate of mortality does not prevail throughout the district, these are but few among many villages similarly affected. These villages are not in the immediate vicinity of one another, but scattered over different and distinct parts of the district, and there can be little doubt that the intervening villages will in due course have their turn of the disease with varying severity.

The Government of Bengal can no longer delay to adopt the most energetic remedies; but it is hoping almost against hope, to think that the calamity can be materially diminished by engineering operations in one or two years.

A Poor-law Medical Officer and the Guardians.

At a recent meeting of the Board of Guardians of the Blackburn Union, Dr. Garstang, one of the medical officers of this Union, tendered his resignation; pending a charge of alleged neglect, which is now under the notice of the Poor-law Board. In announcing his intention to resign, he says to the Guardians, "with all due respect," that there is not one amongst them who knows anything of the actual condition of the sick poor of his district; and that "it may be of interest to you, and to the ratepayers, to be informed that taking into calculation the number of cases, medical, surgical, and obstetric, which I have attended, and the total amount of money which I received, each case, of whatever nature and duration, averages the bewildering sum of 2s." Dr. Garstang further remarks, "It is not at all difficult to realise the sentiment that the pauper doctor is the scapegoat of the Poor-law medical service." Experience but too sadly compels us to endorse this latter passage. The resignation was accepted without discussion.

The Sanitary Condition of the Suez Canal.

M. DE LESSEPS, in his report presented recently to the Company, has expressed himself as follows as to the sanitary state of the population:—

"We have published for distribution the annual report of Dr. Aubert Roche on the sanitary and medical condition of the workmen and officers at the Isthmus. It contains interesting facts. The population, which in 1859 consisted of 150 persons, of whom 25 were Europeans, and 125 natives, amounted last year to 34,258 individuals, 16,010 Europeans, and 18,248 natives, and is at the present moment, altogether, 42,400. The mortality, except that of the cholera year, is maintained at 1 per cent., although in France it amounts to 2·40 per cent. For 10 years since the service has commenced, the health of the people has been steadily improving, and both the diseases and deaths have diminished. But at what a melancholy price has this result been attained! This year four of the medical officers died; out of the eleven medical men who first participated in the enterprise but five remain, the service having lost one-half its number."

An International Pharmacopœia.

AMONGST the questions which are set down for debate at the approaching Pharmaceutical Conference, to be held at Vienna next month, is the compilation of a universal pharmacopœia.

It is desirable to put an end to the inconvenience which accrues when it is desired to make up prescriptions in a foreign country with medicines prepared by a pharmacopœia other than that which is in use in the country of the prescriber.

The Water Commission.

THE evidence has already appeared in a Blue Book of nearly 500 pages. Our readers know much of it in advance. We select for extract, this week, the opinion of Mr. Hawksley, the eminent engineer, who on being asked whether germs of cholera might not be carried from one point to another even in streams, and so purified, replied in the negative. He did not think that cholera was propagated by such means. He said:—"Cholera is a very remarkable disease, and inscrutable as to its origin, but exceedingly rapidly propagated by infection, especially when the disease assumes an epidemic character. In 1853 or 1854, the cholera made an attack upon Newcastle, and it was very fatal there; but there was no cholera at Sunderland. Those two towns are about twelve miles apart in a direct line. Sunderland and Monkwearmouth are practically one town, just as Gateshead and Newcastle are another. There was no cholera at Sunderland, excepting one or two imported cases, but on other occasions there had been a great amount of cholera at Sunderland, and on those occasions there had been comparatively little at Newcastle, although it had never been free. On that occasion (and I am speaking of towns that I have been connected with), after the cholera had done its work at Newcastle, it suddenly jumped over to Bishop's Auckland and settled down there, and was very destructive; then it passed down the river, still omitting Sunderland, and returned upon Durham; but, although these two places are upon the river Wear, Sunderland, which is also upon the river Wear below them, was never attacked. Take Copenhagen also as an example. The cholera twice visited the Baltic, without touching Copenhagen, although Copenhagen was then the worst sewered town perhaps in the world; all the night-soil and garbage were thrown out on the little island called Hamager, adjacent to the town, and the stench from that island pervaded the whole city at night in hot weather. But in 1853 the cholera settled down there like a cloud, not attacking many other places in the Baltic, which it had visited before, and before I left more than 4,000 people had died. No change had occurred in the state of the city or of its water supply on the third visit of the cholera to the Baltic from the state which had prevailed on the first and second visitations. Then again, to show that the water has nothing necessarily to do with it, cholera always follows a certain track; it has its origin in the East Indies, it travels usually through Russia sometimes for two or three years before it reaches England, and it passes always against the prevailing wind. The prevailing wind is westerly, but the cholera comes with the march of the Marmot from place to place almost directly in opposition to it. I am persuaded, and all my experience shows it, that those things to which it has become usual to refer it have nothing to do with the cholera, and that the cholera has nothing to do with them. The cholera germ is a thing of the imagination, inasmuch as nobody has seen it or has been able to watch its development or effects."

Social Science.

THE Congress is to assemble at Bristol on the 27th September, and the discussions will last to the 6th October.

The questions in the Health Department are :—

1. Can Government beneficially further interfere to limit the spread of infectious diseases? 2. What legislative measures might be proposed to deal with cases of uncontrollable drunkenness? 3. Should the Contagious Diseases Act be extended to the civil population?

THE Great Northern Hospital has received an anonymous donation of £1,000.

MR. GEORGE COWELL has been elected Assistant-Surgeon to the Westminster Hospital.

THE New Sydenham Society held its annual meeting at Leeds. It is in a satisfactory condition. Forty volumes have appeared in the ten years. There is usually a balance of £1,000 in hand.

THE *Sind News* of Monday fortnight reports that five deaths from heat-apoplexy occurred at Hyderabad, amongst the detachment of Europeans of H.M.'s 82nd Regiment during the previous fortnight.

MR. D. FERGUSON, the well-known surgical instrument maker to St. Bartholomew's Hospital, died on the 13th inst., at the age of eighty-one. His son had long conducted the business. The deceased gentleman was much respected by his patrons, among whom Lawrence, Vincent, Stanley, and others may be named. He was born at Glasgow in 1789.

WE regret to announce the death of Dr. H. B. Montgomery, Secretary to the Sanitary Commissioner of Madras, and Professor of Hygiene in the Medical College. He died of diarrhœa on the 11th inst. after only a short illness. He entered the service in 1852, when about twenty-six years old. We hear it is probable that the post of Secretary to the Sanitary Commissioner will be abolished. When the Sanitary Commissioner retires from that post, as he will do in a few months on promotion to a higher grade in the medical service, Dr. Montgomery would have probably been appointed Commissioner, and the vacant secretaryship will not be filled up. The principal objection to the proposed reduction is that it will leave no efficient representative of the sanitary department at head quarters during the long tours of the Commissioner.

ACONITE IN TETANUS.

The celebrated Professor Wunderlich reports two cases, one traumatic, the other spontaneous, cured by aconite, in doses of from five to ten drops, from two to four times a day. On the 11th day (in the traumatic case) after twenty-four grammes of the tincture had been used, a cure was effected. In the idiopathic case the treatment was not commenced till the thirteenth day, when five drops, *ter die*, were given. The improvement was very marked on the second day, and a cure followed after eleven grammes of the tincture had been used. Wunderlich regarded the cases as severe.—*Schmidt Jahrb.*

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE Association met at Exeter last Wednesday, according to the programme published in our last number. The proceedings are, of course, extremely lengthy, and cannot be summarised for this issue. We give, as is our custom, the inaugural address of the new President, Professor Stokes, of Cambridge, who, having assumed the Chair, spoke as follows :—

“As this is the first time that the British Association for the Advancement of Science has met in the city of Exeter, and it is probable that many now present have never attended a former meeting, I hope the older members of the Association will bear with me if I say a few words in explanation of the objects for which the Association was instituted. In the first place, then, it aims at fulfilling an office which is quite distinct from that of the various scientific societies which are established in different parts of the country. These, for the most part, have for their leading object to make the voluntary labours of isolated workers in science available to the scientific world generally by receiving, discussing, and publishing the results which they may have obtained. The British Association, on the other hand, aims at giving a more systematic direction to scientific inquiry, and that in various ways.

“In a rapidly progressing branch of science it is by no means easy to become acquainted with its actual state. The workers in it are scattered throughout the civilized world, and their results are published in a variety of Transactions and scientific periodicals, mixed with other scientific matter. To make oneself, without assistance, well acquainted with what has been done, it is requisite to have access to an extensive library, to be able to read with facility several modern languages, and to have leisure to hunt through the tables of contents, or at least the indices, of a number of serial works. Without such knowledge, there is always the risk that a scientific man may spend his strength in doing over again what has been done already; whereas with better direction the same expenditure of time and labour might have resulted in some substantial addition to our knowledge. With a view to meet this difficulty, the British Association has requested individuals who were more specially conversant with particular departments of science, to draw up reports on the present state of our knowledge in, or on the recent progress of, special branches; and the influence of the Association as a public body has been found sufficient to induce a number of scientific men to undertake the great labour of preparing such reports.

“By thus ascertaining thoroughly what we already had, what we still wanted was made more clear; and indeed it was one special object of the reports I have mentioned to point out what were the more prominent desiderata in the various subjects to which they related. The Association was thus the better enabled to fulfil another of its functions, that of organising means for the prosecution of researches which require co-operation. When the want is within the compass of what can be accomplished by individuals, the demand may be left to create the supply, but it often happens that a research can hardly be carried out without co-operation. It may, for instance, require a combination of the most profound theoretical knowledge with the greatest experimental skill, or an extensive knowledge of very dissimilar branches of science; or again, the work to be done, though all of one kind, may be of such an extent as to be beyond the power of any one man. In such cases the limited power of the individual can only be supplemented by the principle of co-operation; and accordingly it becomes an important part of the business of the Association to organise committees for the prosecution of special researches. The researches thus undertaken at the request of the Association are published at length, along with the reports on the progress of science in the first part of the annual volume.

“In close connection with the last must be mentioned another mode in which the Association contributes to the progress of science. Many researches require not only time and thought, but pecuniary outlay; and it would seem hard that scientific men who give their time and labour gratuitously to carrying out such researches should be further obliged to incur an expenditure which they often can ill afford. The Association accordingly grants sums of money to individuals or com-

mittées for defraying the expenses of such researches. It appears from the report which has just been published that, reckoning up to the year 1867 inclusive, £29,312 4s. 1d. has been voted by the Association for various scientific objects. Deducting from this the sum of £23 16s. for the balances of grants not wholly expended, which were returned to the Association, we may say that £29,288 8s. 1d. has been expended in the manner indicated. When we remember that these grants were mostly of small amount, and do not include personal expenses, and that very many of the researches undertaken at the request of the Association do not involve money grants at all, we may form some idea of the amount of scientific activity which has been evoked under the auspices of the Association.

"In the address with which the business of the meeting is opened it is usual for your president to give some account of the most recent progress of science. The task is by no means an easy one. Few indeed are familiar with science in all its branches; and even to one who was, the selection of topics and the mode of treating them would still present difficulties. I shall not attempt to give an account of the recent progress of science in general, but shall select from those branches with which I am more familiar some examples of recent progress which may, I hope, prove to be of pretty general interest. And even in this I feel that I shall have to crave your indulgence, for it is hard to be intelligible to some without being wearisome to others.

"Among the various branches of physical science, astronomy occupies in many respects a foremost rank. The movements of the heavenly bodies must have occupied the attention and excited the interest of mankind from the earliest ages, and accordingly the first rudiments of science are lost in the depths of antiquity. The grandeur of the subjects of contemplation which it presents to us have won for it especial favour, and its importance in relation to navigation has caused it to be supported by national resources. Newton's great discovery of universal gravitation raised it from the rank of a science of observation to that of one admitting of the most exact mathematical deduction; and the investigation of the consequences of this law, and the explanation thereby of the lunar and planetary disturbances, have afforded a field for the exercise of the highest mathematical powers on the part of Newton and his successors. Gradually the apparent anomalies, as they might have been deemed, in the motions of the heavenly bodies were shown to be necessary consequences of the one fundamental law, and at last, as the result of calculations of enormous labour, tables were constructed enabling the places of those bodies at any given time to be determined years beforehand with astonishing precision. A still more striking step was taken. When it had been shown by careful calculation that the apparent motion of the remotest of the planets then known to belong to our system could not be wholly explained on the theory of gravitation, by taking account of the disturbing powers of the other known planets, Adams in our own country, and Le Verrier in France, boldly reversed the problem, and instead of determining the disturbing effect of a known planet, set themselves to inquire what must be the mass and orbit of an unknown planet which shall be capable of producing by its disturbing force the unexplained deviations in the position of Uranus from its calculated place. The result of this inquiry is too well known to require notice.

"After these brilliant achievements some may perhaps have been tempted to imagine that the field of astronomical research must have been well-nigh exhausted. Small perturbations, hitherto overlooked, might be determined, and astronomical tables thereby rendered still more exact. New asteroids might be discovered by the telescope. More accurate values of the constants with which we have to deal might be obtained. But no essential novelty of principle was to be looked for in the department of astronomy; for such we must go to younger and less mature branches of science.

"Researches which have been carried on within the last few years, even the progress which has been made within the last twelve months, show how short-sighted such an anticipation would have been; what an unexpected flood of light may sometimes be thrown over one science by its union with another; how conducive accordingly to the advancement of science may be an association like the present, in which not only are the workers at special sciences brought together in the sectional meetings, but in the general meetings of the Association, and in the social intercourse, which, though of an informal character, is no unimportant part of our proceedings, the cultivators of different branches of science brought together, and

have an opportunity of enlarging their minds by contact with the minds of others, who have been used to trains of thought of a very different character from their own.

"The science of astronomy is indebted to that of optics for the principles which regulate the construction of those optical instruments which are so essential to the astronomer. It repaid its debt by furnishing to optics a result which it is important we should keep in view in considering the nature of light. It is to astronomy that we are indebted for the first proof we obtained of the finite velocity of light, and for the first numerical determination of that enormous velocity. Astronomy, again, led, 44 years later, to a second determination of that velocity in the remarkable phenomenon of aberration discovered by Bradley, a phenomenon presenting special points of interest in relation to the nature of light, and which has given rise to some discussion extending even to the present day, so that the Astronomer Royal has not deemed it unworthy of investigation, laborious as he foresees the trial is likely to prove to determine the constant of aberration by means of a telescope having its tube filled with water.

"If in respect of these phenomena optics received much aid from astronomy, the latter science has been indebted to the former for information which could not otherwise have been obtained. The motions and the masses of the heavenly bodies are revealed to us more or less fully by astronomical observations; but we could not thus become acquainted with the chemical nature of these distant objects. Yet, by the application of the spectroscope to the scrutiny of the heavenly bodies, evidence has been obtained of the existence therein of various elements known to us by the chemical examination of the materials of which our own earth is composed; and not only so, but light is thrown on the state in which matter is there existing, which, in the case of nebulae especially, led to the formation of new ideas respecting their constitution, and the rectification of astronomical speculations previously entertained. I shall not, however, dwell further on this part of the subject, which is now of some years' standing, and has been mentioned by more than one of your former presidents, but will pass on to newer researches in the same direction.

"We are accustomed to apply to the stars the epithet fixed. Night after night they are seen to have the same relative arrangement; and when their places are determined by careful measurement, and certain small corrections due to known causes are applied to the immediate results of observation, they are found to have the same relative distances. But when instead of days the observations extend over months or years, it is found that the fixity is not quite absolute. Defining as fixity invariability of position as estimated with reference to the stars as a whole, and comparing the position of an individual star with those of the stars in its neighbourhood, we find that some of the stars exhibit 'proper motions,' show, that is, a progressive change of angular position as seen from the earth, or rather as they would be seen from the sun, which we may take for the mean annual place of the earth. This indicates linear motion in a direction transverse to the line joining the sun with the star. But since our sun is merely a star, a line drawn from the star exhibiting proper motion to our sun is, as regards the former, merely a line drawn to a star taken at random, and therefore there is no reason why the star's motion should be, except accidentally, in a direction perpendicular to the line joining the star with our sun. We must conclude that the stars, including our own sun, or some of them at least, are moving in various directions in space, and that it is merely the transversal component of the whole motion, or rather of the motion relatively to our sun, that is revealed to us by a change in the star's apparent place.

"How then shall we determine whether any particular star is approaching to or receding from our sun? It is clear that astronomy alone is powerless to aid us here, since such a motion would be unaccompanied by change of angular position. Here the science of optics comes to our aid in a remarkable manner.

"The pitch of a musical note depends, as we know, on the number of vibrations which reach the ear in a given time, such as a second. Suppose, now, that a body, such as a bell, which is vibrating a given number of times per second, is at the same time moving from the observer, the air being calm. Since the successive pulses of sound travel all with the velocity of sound, but diverge from different centres, namely, the successive points in the bell's path at which the bell was when those pulses were first excited, it is evident that the sound-waves will be somewhat more spread out on the side from which the bell is moving, and more crowded together on the side towards which it is moving, than if the bell had been at

rest. Consequently the number of vibrations per second which reach the ear of an observer situated in the former of these directions will be somewhat smaller, and the number which reach an observer situated in the opposite direction somewhat greater than if the bell had been at rest. Hence to the former the pitch will be somewhat lower, and to the latter somewhat higher, than the natural pitch of the bell. And the same thing will happen if the observer be in motion instead of the bell, or if both be in motion; in fact, the effect depends only on the relative motion of the observer and the bell in the direction of a line joining the two—in other words, on the velocity of recession or approach of the observer and the bell. The effect may be perceived in standing by a railway when a train in which the steam whistle is sounding passes by at full speed, or, better still, if the observer be seated in a train which is simultaneously moving in the opposite direction.

"The present state of optical science is such as to furnish us with evidence of a force which is perfectly overwhelming, that light consists of a tremor or vibratory movement propagated in an elastic medium filling the planetary and stellar places, a medium which thus fulfils for light an office similar to that of air for sound. In this theory, to difference of periodic time corresponds difference of refrangibility. Suppose that we were in possession of a source of light capable, like the bell in the analogous case of sound, of exciting in the æther supposed at rest vibrations of a definite period, corresponding, therefore, to light of a definite refrangibility. Then, just as in the case of sound, if the source of light and the observer were receding from or approaching to each other with a velocity which was not insensibly small compared with the velocity of light, an appreciable lowering or elevation of refrangibility would be produced, which would be capable of detection by means of a spectroscope of high dispersive power.

"The velocity of light is so enormous—about 185,000 miles per second—that it can readily be imagined that any motion which we can experimentally produce in a source of light is as rest in comparison. But the earth in its orbit round the sun moves at the rate of about 18 miles per second; and in the motions of stars approaching to or receding from our sun we might expect to meet with velocities comparable with this. The orbital velocity of the earth is, it is true, only about the one ten-thousandth part of the velocity of light, which admits of being easily calculated, proves not to be so insensibly small as to elude all chance of detection, provided only the observations are conducted with extreme delicacy.

"But how shall we find in such distant objects as the stars an analogue of the bell which we have assumed in the illustration drawn from sound? What evidence can we ever obtain, if an examination of their light should present us with rays of definite refrangibility, of the existence in those remote bodies of ponderable matter vibrating in known periods not identical with those corresponding to the refrangibilities of the definite rays which we observe? The answer to this question will involve a reference, which I will endeavour to make as brief as I can, to the splendid researches of Professor Kirchhoff. The exact coincidence of certain dark lines in the solar spectrum with bright lines in certain artificial sources of light had previously been in one or two instances observed; but it is to Kirchhoff we owe the inference from an extension of Prevost's theory of exchanges, that a glowing medium which emits bright light of any particular refrangibility necessarily (at that temperature at least) acts as an absorbing medium, extinguishing light of the same refrangibility. In saying this it is but just to mention that in relation to radiant heat (from whence the transition to light is easy), Kirchhoff was preceded, though unconsciously, by our own countryman, Mr. Balfour Stewart. The inference which Kirchhoff drew from Prevost's theory thus extended led him to make a careful comparison of the places of the dark lines of the solar spectrum with those of bright lines produced by the incandescent gas or vapour of known elements; and the coincidences were in many cases so remarkable as to establish almost to a certainty the existence of several of the known elements in the solar atmosphere, producing by their absorbing action the dark lines coinciding with the bright lines observed. Among other elements may be mentioned in particular hydrogen, the spectrum of which, when traversed by an electric discharge, shows a bright line or band exactly coinciding with the dark line C, and another with the line F.

"Now Mr. Huggins found that several of the stars show in their spectra dark lines coinciding in position with C and F; and what strengthens the belief that this coincidence, or apparent coincidence, is not merely fortuitous, but is due to a

common cause, is that the two lines are found associated together, both present or both absent. And Kirchhoff's theory suggests that the common cause is the existence of hydrogen in the atmospheres of the sun and certain stars, and its exercise of an absorbing action on the light emitted from beneath.

"Now, by careful and repeated observations with a telescope furnished with a spectroscope of high dispersive power, Mr. Huggins found that the F line, the one selected for observation, in the spectrum of Sirius, did not exactly coincide with the corresponding bright line of a hydrogen spark, which latter agrees in position with the solar F, but was a little less refrangible, while preserving the same general appearance. What conclusion, then, are we to draw from the result? Surely it would be most unreasonable to attribute the dark lines in the spectra of the sun and of Sirius to distinct causes, and to regard their almost exact coincidence as purely fortuitous, when we have in proper motion a *vera causa* to account for a minute difference. And if, as Kirchhoff's labours render almost certain, the dark solar line depends on the existence of hydrogen in the atmosphere of our sun, we are led to infer that that element, with which the chemist working in his laboratory is so familiar, exists and is subject to the same physical laws in that distant star, so distant that, judging by the most probable value of its annual parallax, light which would go seven times round our earth in one second would take fourteen years to travel from the star. What a grand conception of the unity of plan pervading the universe do such conclusions present to our minds!

"Assuming, then, that the small difference of refrangibility observed between the solar F and that of Sirius is due to proper motion, Mr. Huggins concludes from his measures of the minute difference of position that at the time of the observation Sirius was receding from the earth at the rate of 41.4 miles per second. A part of this was due to the motion of the earth in its orbit; and on deducting the orbital velocity of the earth, resolved in the direction of a line drawn from the star, there remained 29.4 miles per second as the velocity with which Sirius and our sun are mutually receding from each other. Considering the minuteness of the quantity on which the result depends, it is satisfactory to find that Mr. Huggins's results as to the motion of Sirius have been confirmed by the observations of Father Secchi, made at Rome with a different instrument.

"The determination of radial proper motion in this way is still in its infancy. It is worthy of note that, unlike the detection of transversal proper motion by change of angular position, it is equally applicable to stars at all distances, provided they are bright enough to render the observations possible. It is conceivable that the results of these observations may one day lead to a determination of the motion of the solar system in space, which is more trustworthy than that which has been deduced from changes of position, as being founded on a broader induction, and not confined to conclusions derived from the stars in our neighbourhood. Should even the solar system and the nearer stars be drifting along, as Sir John Herschel suggests, with an approximately common motion, like motes in a sunbeam, it is conceivable that the circumstance might thus be capable of detection. To what wide speculations are we led as to the possible progress of our knowledge when we put together what has been accomplished in different branches of science!

"I turn now to another recent application of spectral analysis. The phenomenon of a total solar eclipse is described by those who have seen it as one of the most imposing that can be witnessed. The rarity of its occurrence and the shortness of its duration afford, however, opportunity for only a hasty study of the phenomena which may then present themselves. Among these, one of the most remarkable, seen indeed before, but first brought prominently into notice by the observers who watched the eclipse of July 7, 1842, consists in a series of mountain-like or cloud-like luminous objects seen outside the dark disc of the moon. These have been seen in subsequent total eclipses, and more specially studied, by means of photography, by Mr. Warren De La Rue in the eclipse of June 18, 1860. The result of the various observations, and especially the study, which could be made at leisure, of the photographs obtained by Mr. De La Rue, proved conclusively that these appendages belong to the sun, not to the moon. The photographs proved, further, their light to be remarkable for actinic power. Since that time the method of spectral analysis has been elaborated, and it seemed likely that additional information bearing on the nature of these objects, might be obtained by the application of the spectroscope. Accordingly, various

expeditions were equipped for the purpose of observing the total solar eclipse which was to happen on August 17, 1868. In our own country an equatorially mounted telescope provided with a spectroscope was procured for the purpose by the Royal Society, which was entrusted to Lieutenant (now Captain) Herschel, who was going out to India, one of the countries crossed by the line of the central shadow. Another expedition was organised by the Royal Astronomical Society, under the auspices of Major Tennant, who was foremost in pressing on the attention of scientific men the importance of availing themselves of the opportunity.

"Shortly before the conclusion of the meeting of the Association at Norwich last year, the first results of the observations were made known to the meeting through the agency of the electric telegraph. In a telegram sent by M. Janssen to the president of the Royal Society, it was announced that the spectrum of the prominences was very remarkable, showing bright lines, while that of the corona showed none. Brief as the message necessarily was, one point was settled. The prominences could not be clouds in the strict sense of the term, shining either by virtue of their own heat or by light reflected from below. They must consist of incandescent matter in the gaseous form. It appeared from the more detailed accounts received by post from the various observers, and put together at leisure, that except in the immediate neighbourhood of the sun, the light of the prominences consisted mainly of three bright lines, of which two coincided with C and F, and the intermediate one nearly, but, as subsequent researches showed, not exactly, with D. The bright lines coinciding with C and F indicate the presence of glowing hydrogen. Several of the other lines were identified with those which would be produced by the incandescent vapour of certain other elements.

"This is precious information to have gathered during the brief interval of the total phase, and required on the part of the observers self-denial in withdrawing the eye from the imposing spectacle of the surrounding scenery, and coolness in proceeding steadily with some definite part of the inquiry, when so many questions crowded for solution, and the fruits of months of preparation were to be reaped in three or four minutes or lost altogether; especially when, as too often happened, the observations were provokingly interrupted by flying clouds.

"But valuable as these observations were, it is obvious that we should have had long to wait before we could have become acquainted with the usual behaviour of these objects, and their possible relation to changes which may be going on at the surface of the sun, if we had been dependent on the rare and brief phenomenon of a total solar eclipse for gathering information respecting them. But how, the question might be asked, shall we ever be able so to subdue the overpowering glare of our great luminary, and the dazzling illumination which it produces in our atmosphere, when we look nearly in its direction, as to perceive objects which are comparatively so faint? Here again the science of optics comes in aid of astronomy.

"When a line of light, such as a narrow slit held in front of a luminous object, is viewed through a prism, the light is ordinarily spread out into a coloured band, the length of which may be increased at pleasure by substituting two or more prisms for the single prism. As the total quantity of light is not thereby increased it is obvious that the intensity of the light of the coloured band will go on decreasing as the length increases. Such is the case with ordinary sources of light, like the flame of a candle, or the sky, which gives a continuous spectrum, or one generally continuous though interrupted by dark bands. But if the light from the source be homogeneous, consisting, that is, of light of one degree of refrangibility only, the image of the slit will be merely deviated by the prisms, not widened out into a band, and not consequently reduced in intensity by the dispersion. And if the source of light emit light of both kinds it will be easily understood that the images of the slit corresponding to light of any definite refrangibilities which the mixture may contain will stand out, by their superior intensity, on the weaker ground of the continuous spectrum.

"Preparations for observations of this kind had long been in progress in the hands of our countryman Mr. Lockyer. His first attempts were unsuccessful; but, undismayed by failure, he ordered the construction of a new spectroscope of superior power, in which he was aided by a grant from the sum placed annually by Parliament at the disposal of the Royal Society for scientific purposes. The execution of this instrument was delayed by what proved to be the last illness of the eminent optician to whom it was entrusted, the late Mr. Cooke; but when at last the instrument was placed in his

hands, Mr. Lockyer was not long in discovering the object of his two years' search. On the 20th of October last year, in examining the space immediately surrounding the edge of the solar disc, he obtained evidence, by the occurrence of a bright line in the spectrum, that his slit was on the image of one of those prominences the nature of which had so long been an enigma. It further appeared from an observation made on November 5 (as indeed might be expected from the photographs of Mr. De La Rue, and the descriptions of those who had observed total solar eclipses) that the prominences were merely elevated portions of an extensive luminous stratum of the same general character, which, now that the necessity of the interposition of the moon was dispensed with, could be traced completely round the sun. Notices of this discovery were received from the author by the Royal Society on Oct. 21 and Nov. 3, and the former was almost immediately published in No. 105 of the Proceedings. These were shortly afterwards followed by a fuller paper on the same subject.

"Meanwhile the same thing had been independently observed in another part of the world. After having observed the remarkable spectrum of the prominences during the total eclipse, it occurred to M. Janssen that the same method might allow the prominences to be detected at any time; and on trial he succeeded in detecting them the very day after the eclipse. The results of his observations were sent by post, and were received shortly after the account of Mr. Lockyer's discovery had been communicated by Mr. De La Rue to the French Academy.

"In the way hitherto described a prominence is not seen as a whole, but the observer knows when its image is intercepted by the slit; and by varying a little the position of the slit a series of sections of the prominence are obtained, by putting which together the form of the prominence is deduced. Shortly after Mr. Lockyer's communication of his discovery, Mr. Huggins, who had been independently engaged in the attempt to render the prominences visible by the aid of the spectroscope, succeeded in seeing a prominence as a whole by somewhat widening the slit, and using a red glass to diminish the glare of the light admitted by the slit, the prominence being seen by means of the C line in the red. Mr. Lockyer had a design for seeing the prominences as a whole by giving the slit a rapid motion of small extent, but this proved to be superfluous, and they are now habitually seen with their actual forms. Nor is our power of observing them restricted to those which are so situated that they are seen by projection outside the sun's limb; such is the power of the spectroscopic method of observation that it has enabled Mr. Lockyer and others to observe them right on the disc of the sun, an important step for connecting them with other solar phenomena.

"One of the most striking results of the habitual study of these prominences is the evidence they afford of the stupendous changes which are going on in the central body of our system. Prominences the heights of which are to be measured by thousands and tens of thousands of miles appear and disappear in the course of some minutes. And a study of certain minute changes of position in the bright line F, which receive a simple and natural explanation by referring them to proper motion in the glowing gas by which that line is produced, and which we see no other way of accounting for, have led Mr. Lockyer to conclude that the gas in question is sometimes travelling with velocities comparable with that of the earth in its orbit. Moreover, these exhibitions of intense action are frequently found to be intimately connected with the spots, and can hardly fail to throw light on the disputed question of their formation. Nor are chemical composition and proper motion the only physical conditions of the gas which are accessible to spectral analysis. By comparing the breadth of the bright bands (for though narrow they are not mere lines) seen in the prominences with those observed in the spectrum of hydrogen rendered incandescent under different physical conditions, Dr. Frankland and Mr. Lockyer have deduced conclusions respecting the pressure to which the gas is subject in the neighbourhood of the sun. I am happy to say that Mr. Lockyer has consented to deliver a discourse during our meeting, in which the whole subject will doubtless be fully explained.

"I have dwelt perhaps too long on this topic, and I cannot help fearing that I may have been tedious to the many scientific men to whom the subject is already perfectly familiar. Yet the contemplations which it opens out to us are so exalted, and the proof which it affords of what can be accomplished by the union of different branches of science is so striking, that I hope I may be pardoned for occupying your time. I cannot, however, leave the subject of astronomy without congratu-

lating the Association on the accomplishment of an object which originated with it, and in the promotion of which it formerly took an active part. It was at the meeting of the Association at Birmingham, in 1849, under the presidency of the Rev. Dr. Robinson, that a resolution was passed for making an application to Her Majesty's Government to establish a reflector of not less than three feet aperture at the Cape of Good Hope, and to make such additions to the staff of that observatory as might be necessary for its effectual working. This resolution met with the hearty concurrence of the President of the Council of the Royal Society, who suggested that the precise locality in the Southern Hemisphere where the telescope should be erected had best be left an open question. This modification having been adopted by your council, the application was presented to Earl Russell, then First Lord of the Treasury, by representatives of both bodies early in 1850. A reply was received from Government to the effect that though they agreed with the Association as to the interest which attached itself to the inquiry, yet there was so much difficulty attending the arrangements that they were not prepared to take any steps without much further inquiry. This reply was considered so far favourable as not to forbid the hope of success if the application were renewed on a suitable opportunity. The subject was again brought before the Association by Colonel (now General Sir Edward) Sabine, in his opening address as president at the Belfast meeting in 1852. The result was that the matter was again brought before Government by a committee of the British Association acting in conjunction with a committee of the Royal Society, by means of an application made to the Earl of Aberdeen. By this time the country was engaged in the Russian war, in consequence of which, it was replied, no funds could then be spared; but a promise was given that when the crisis then impending was past the matter should be taken up, a promise which the retirement from office and subsequent death of Lord Aberdeen rendered of no avail.

"But though failing in its immediate object, the action of the British Association in this matter has not remained fruitless. A few years later the subject was warmly taken up at Melbourne, and after preliminary correspondence between the board of visitors of the Melbourne Observatory and the president and council of the Royal Society, and the appointment by the latter body of a committee to consider and report on the subject, in April, 1864, a proposition was made to the colonial legislature for a grant of £5,000 for the construction of a telescope, and was acceded to. Not to weary you with details, I will merely say that the telescope has been constructed by Mr. Grubb, of Dublin, and is now erected at Melbourne, and in the hands of Mr. Le Suer, who has been appointed to use it. It is a reflector of four feet aperture, of the Cassegrain construction, equatorially mounted, and provided with a clock movement. Before its shipment it was inspected in Dublin by the committee appointed by the Royal Society to consider the best mode of carrying out the object for which the vote was made by the Melbourne Legislature; and the committee speak in the highest terms of its contrivance and execution. We may expect before long to get a first instalment of the results obtained by a scrutiny of the southern heavens with an instrument far more powerful than any that has hitherto been applied to them—results which will at the same time add to our existing knowledge and redound to the honour of the colony, by whose liberality this long-cherished object has at last been effected.

"As I have mentioned an application to the Government on the part of the Association which was not successful, it is but right to say that such is not generally the result. I will refer to one instance. At the Cambridge meeting of the Association, in 1862, a committee, consisting of representatives of the mechanical and chemical sections, was appointed for the purpose of investigating the application of gun-cotton to warlike purposes. At the Newcastle meeting, in the following year, this committee presented their report. It was felt that a complete study of the subject demanded appliances which could be obtained only from our military resources, and at the Newcastle meeting a resolution was passed recommending the appointment of a Royal commission. The recommendation was adopted, and in 1864 a commission was appointed, which was requested to report on the application of gun-cotton to civil as well as to naval and military purposes. The committee gave in their report last year, and that report, together with a more recent return relative to the application of gun-cotton to mining and quarrying operations, has just been printed for the House of Commons.

"A substance of such comparatively recent introduction cannot be fairly compared with an explosive in the use of which we have the experience of centuries. Yet, even with our present experience, there are some purposes for which gun-cotton can advantageously replace gunpowder, while its manufacture and storage can be effected with comparative safety, since it is in a wet state during the process of manufacture, and is not at all injured by being kept permanently in water, but merely requires to be dried for use. Even should it be required to store it in the dry state, it is doubtful whether, with the precautions indicated by the chemical investigations of Mr. Abel, any greater risk is incurred than in the case of gunpowder. In the blasting of hard rocks it is found to be highly efficient, while the remarkable results recently obtained by Mr. Abel leave no doubt of its value for explosions such as are frequently required in warfare. General Hay speaks highly of the promise of its value for small arms; but many more experiments are required, especially as a change in the arm and mode of ignition require a change in the construction of the cartridge. In heavy ordnance the due control of the rapidity of combustion of the substance is a matter of greater difficulty; and, though considerable progress has been made, much remains to be done before the three conditions of safety to the gun, high velocity of projection, and uniformity of result are satisfactorily combined.

"By the kindness of Dr. Carpenter I am enabled to mention to you the latest results obtained in an expedition which could not have been undertaken without the aid of Government, an aid which was freely given. Last year Dr. Carpenter and Professor Wyville Thomson represented to the president and council of the Royal Society the great importance to zoology and paleontology of obtaining soundings from great depths in the ocean, and suggested to them to use their influence with the Admiralty to induce them to place a gun-boat, or other suitable vessel, at the disposal of those gentlemen and any other naturalists who might be willing to accompany them, for the purpose of carrying on a systematic course of deep-sea dredging for a month or six weeks. This application was forwarded to the Admiralty with the warm support of the president and council, and was readily acceded to. The operations were a good deal impeded by rough weather, but, nevertheless, important results were obtained. Dredging was successfully accomplished at a depth of 650 fathoms; and the existence was established of a varied and abundant submarine fauna, at depths which had generally been supposed to be either azoic, or occupied by animals of a very low type; and the character of the fauna and of the mud brought up was such as to point to a chalk formation actually going on.

"It seemed desirable to carry the soundings to still greater depths, and to examine more fully the changes of temperature which had been met with in the descent. Another application was accordingly made to the Admiralty in the present year, and was no less readily acceded to than the former; and a larger vessel than that used last year is now on her cruise. I am informed by Dr. Carpenter that dredging has been successfully carried down to more than 2,400 fathoms (nearly the height of Mont Blanc), and that animal life has been found even at that depth in considerable variety, though its amount and kind are obviously influenced by the reduction of temperature to Arctic coldness. A very careful series of temperature soundings has been taken, showing, on the same spot, a continuous descent of temperature with the depth, at first more rapid, afterwards pretty uniform. Thermometers protected from pressure by a plan described by Dr. Miller were found to maintain their character at the great depths reached, the difference between them and the best ordinary thermometers used in the same sounding being exactly conformable to the pressure corresponding with each depth, as determined by the experiments previously made in smaller depths. All the observations hitherto made go to confirm the idea of a general interchange of polar and equatorial water, the former occupying the lowest depths, the latter forming a superficial stratum of 700 or 800 fathoms. The analyses of the water brought up indicate a large proportion of carbonic acid in the gases of the deep waters, and a general diffusion of organic matter.

"I must turn for a few moments to another application recently made to Government, which has not been successful. The application I have in view was made, not by the British Association, or other scientific societies in their corporate capacity, but by a body composed of the presidents of the British Association and of the Royal and other leading scientific societies, and its object was, not the promotion of science

directly, but the recognition of pre-eminent scientific merit. In the history of science few names, indeed, hold so prominent a place as that of Faraday. The perfect novelty of principle and recondite nature of many of his great discoveries are such as to bear the impress of genits of the highest order, and to form an epoch in the advance of science, and while his scientific labours excited the admiration of men of science throughout the world, his singularly genial disposition and modest unassuming character won for him the love of those who had the happiness of numbering him among their personal friends. At a meeting of the presidents of the scientific societies to which I have alluded, it was resolved to erect a marble statue in memory of Faraday. He was a man of whom England may well be proud, and it was thought that it would be a graceful recognition of his merits if the monument were erected at the public expense. The present Chancellor of the Exchequer, however, did not think it right that the recognition of scientific merit, however eminent, should fall on the taxation of the country, though even in a pecuniary point of view the country has received so much benefit from the labours of scientific men. The carrying out of the resolution being thus left to private exertion, a public meeting, presided over by his Royal Highness the Prince of Wales, was held in the Royal Institution, an establishment which has the honour of being identified with Faraday's scientific career. At this meeting a committee was formed to carry out the object, and a subscription list commenced. By permission of the secretaries of this Association an office has been opened in the reception-room, where those members of the Association who may be desirous of taking part in the movement will have every facility afforded them.

"In chemistry I do not believe that any great step has been made within the last year; but perhaps there is no science in which an earnest worker is so sure of being rewarded by making some substantial acquisition to our knowledge, though it may not be of the nature of one of those grand discoveries which from time to time stamp their impress on different branches of science. I may be permitted to refer to one or two discoveries which are exceedingly curious, and some of which may prove of considerable practical importance.

"The Turaco, or plantain-eater of the Cape of Good Hope, is celebrated for its beautiful plumage. A portion of the wings is of a fine red colour. This red-colouring matter has been investigated by Professor Church, who finds it to contain nearly six per cent. of copper, which cannot be distinguished by the ordinary tests, nor removed from the colouring-matter without destroying it. The colouring-matter is in fact a natural organic compound of which copper is one of the essential constituents. Traces of this metal had previously been found in animals—for example, in oysters, to the cost of those who partook of them. But in these cases the presence of the copper was merely accidental; thus oysters that lived near the mouths of streams which came down from copper mines assimilated a portion of the copper salt, without apparently its doing them either good or harm. But in the Turaco the existence of the red colouring matter which belongs to their normal plumage is dependant upon copper, which, obtained in minute quantities with the food, is stored up in this strange manner in the system of the animal. Thus in the very same feather, partly red and partly black, copper was found in abundance in the red parts, but none or only the merest trace in the black.

"This example warns us against taking too utilitarian a view of the plan of creation. Here we have a chemical substance elaborated, which is perfectly unique in its nature, and contains a metal, the salts of which are ordinarily regarded as poisonous to animals; and the sole purpose to which, so far as we know, it is subservient in the animal economy is one of pure decoration. Thus a pair of the birds which were kept in captivity lost their fine red colour, in the course of a few days, in consequence of washing in the water which was left them to drink, the red-colouring matter, which is soluble in water, being thus washed out, but except as to the loss of their beauty it does not appear that the birds were the worse for it.

"A large part of the calicoes which are produced in this country in such enormous quantities are sent out into the market in the printed form. Although other substances are employed, the place which madder occupies among dyestuffs with the calico-printer is compared by Mr. Shunck to that which iron occupies among metals with the engineer. It appears from the public returns that upwards of 10,000 tons of madder are imported annually into the United King-

dom. The colours which madder yields to mordanted cloth are due to two substances, alizarine and purpurine, derived from the root. Of these, alizarine is deemed the more important, as producing faster colours, and yielding finer violets. In studying the transformations of alizarine under the action of chemical re-agents, MM. Graebe and Liebermann were led to connect it with anthracene, one of the coal-tar series of bodies, and to devise a mode of forming it artificially. The discovery is still too recent to allow us to judge of the cost with which it can be obtained by artificial formation, which must decide the question of its commercial employment. But assuming it to be thus obtained at a sufficiently cheap rate, what a remarkable example does the discovery afford of the way in which the philosopher quietly working in his laboratory may obtain results which revolutionise the industry of nations! To the calico-printer, indeed, it may make no very important difference whether he continues to use madder, or replaces it by the artificial substance; but what a sweeping change is made in the madder-growing interest! What hundreds of acres hitherto employed in madder cultivation are set free for the production of human food, or of some other substance useful to man! Such changes can hardly be made without temporary inconvenience to those who are interested in the branches of industry affected; but we must not on that account attempt to stay the progress of discovery, which is conducive to the general weal.

"Another example of the way in which practical applications unexpectedly turn up when science is pursued for its own sake is afforded by a result recently obtained by Dr. Matthiessen, in his investigation of the constitution of the opium bases. He found that by the action of hydrochloric acid on morphia a new base was produced, which as to composition differed from the former merely by the removal of one equivalent of water. But the physiological action of the new base was utterly different from that of the original one. While morphia is a powerful narcotic, the use of which is apt to be followed by subsequent depression, the new base was found to be free from narcotic properties, but to be a powerful emetic, the action of which was unattended by injurious after-effects. It seems likely to become a valuable remedial agent.

"In relation to mechanism, this year is remarkable as being the centenary of the great invention of our countryman James Watt. It was in the year 1769 that he took out his patent involving the invention of separate condensation, which is justly regarded as forming the birth of the steam-engine. Little could even his inventive mind have foreseen the magnitude of the gift he was conferring on mankind in general, and on his own country more particularly. In these days of steamers, power-looms, and railways, it requires no small effort to place ourselves in imagination in the condition we should be in without the steam-engine. It needs no formal celebration to remind Britons what they owe to Watt. Of him truly it may be said, '*Si monumentum requiris, circumspice.*'

"With reference to those branches of science in which we are more or less concerned with the phenomena of life, my own studies give me no right to address you. I regret this the less because my predecessor and my probable successor in the presidential chair are both of well-known eminence in this department. But I hope I may be permitted as a physicist, and viewing the question from the physical side, to express to you my views as to the relation which the physical bear to the biological sciences.

"No other physical science has been brought to such perfection as mechanics; and in mechanics we have long been familiar with the idea of the perfect generality of its laws, of their applicability to bodies organic as well as inorganic, living as well as dead. Thus in a railway collision, when a train is suddenly arrested, the passengers are thrown forward by virtue of the inertia of their bodies, precisely according to the laws which regulate the motion of dead matter. So trite has the idea become that the reference to it may seem childish; but from mechanics let us pass on to chemistry, and the case will be found by no means so clear. When chemists ceased to be content with the mere ultimate analysis of organic substances, and set themselves to study their proximate constituents, a great number of definite chemical compounds were obtained which could not be formed artificially. I do not know what may have been the usual opinion at that time among chemists as to their mode of formation. Probably it may have been imagined that chemical affinities

were indeed concerned in their formation, but controlled and modified by an assumed vital force. But as the science progressed many of these organic substances were formed artificially—in some cases from other and perfectly distinct organic substances, in other cases, actually from their elements. This statement must indeed be accepted with one qualification. It was stated several years ago by M. Pasteur, and I believe the statement still remains true, that no substance the solution of which possesses the property of rotating the plane of polarisation of polarised light had been formed artificially from substances not possessing that property. Now several of the natural substances which are deemed to have been produced artificially, are active in the sense of rotating the plane of polarisation; and therefore in these cases the inactive artificial substances cannot be absolutely identical with the natural ones. But the inactivity of the artificial substance is readily explained on the supposition that the artificial substance bears to the natural the same relation as racemic acid bears to tartaric—that it is, so to speak, a mixture of the natural substance with its image in a mirror. And when we remember by what a peculiar and troublesome process M. Pasteur succeeded in separating racemic acid into the right-handed and left-handed tartaric acids, it will be at once understood how easily the fact, if it be a fact, of the existence in the natural substance of a mixture of two substances, one right-handed and the other left-handed, but otherwise identical, may have escaped detection. This is a curious point, to the clearing up of which it is desirable that chemists should direct their attention. Waiving, then, the difference of activity or inactivity, which, as we have seen, admits of a simple physical explanation, though the correctness of that explanation remains to be investigated, we may say that at the present time a considerable number of what used to be regarded as essentially natural organic substances have been formed in the laboratory. That being the case, it seems most reasonable to suppose that in the plant or animal from which those organic substances were obtained they were formed by the play of ordinary chemical affinity, not necessarily nor probably by the same series of reactions by which they were formed in the laboratory, where a high temperature is commonly employed, but still by chemical reaction of some kind, under the agency in many cases of light, an agency sometimes employed by the chemist in his laboratory. And since the boundary line between the natural substances which have and those which have not been formed artificially is one which, so far as we know, simply depends upon the amount of our knowledge, and is continually changing as new processes are discovered, we are led to extend the same reasoning to the various chemical substances of which organic structures are made up.

“But do the laws of chemical affinity, to which, as I have endeavoured to infer, living beings, whether vegetable or animal, are in absolute subjection, together with those of capillary attraction, of diffusion, and so forth, account for the formation of an organic structure, as distinguished from the elaboration of the chemical substances of which it is composed? No more, it seems to me, than the laws of motion account for the union of oxygen and hydrogen to form water, though the ponderable matter so uniting is subject to the laws of motion during the act of union just as well as before and after. In the various processes of crystallisation, of precipitation, and so forth, which we witness in dead matter, I cannot see the faintest shadow of an approach to the formation of an organic structure, still less to the wonderful series of changes which are concerned in the growth and perpetuation of even the lowliest plant. Admitting to the full as highly probable, though not completely demonstrated, the applicability of living beings of the laws which have been ascertained with reference to dead matter, I feel constrained at the same time to admit the existence of a mysterious something lying beyond—a something *sui generis*, which I regard not as balancing and suspending the ordinary physical laws, but as working with them and through them to the attainment of a designed end.

“What this something which we call life may be is a profound mystery. We know not how many links in the chain of secondary causation may yet remain behind; we know not how few. It would be presumptuous indeed to assume in any case that we had already reached the last link, and to charge with irreverence a fellow-worker who attempted to push his investigations yet one step further back. On the other hand, if a thick darkness enshrouds all beyond, we have no right to assume it to be impossible that

we should have reached even the last link of the chain—a stage where further progress is unattainable, and we can only refer the highest law at which we stopped to the fiat of an Almighty Power. To assume the contrary as a matter of necessity, is practically to remove the first cause of all to an infinite distance from us. The boundary, however, between what is clearly known and what is veiled in impenetrable darkness is not ordinarily thus sharply defined. Between the two there lies a misty region, in which loom the ill-discerned forms of links of the chain which are yet beyond us. But the general principle is not affected thereby. Let us fearlessly trace the dependence of link on link, as far as it may be given us to trace it, but let us take heed that in thus studying second causes we forget not the first cause, nor shut our eyes to the wonderful proofs of design which, in the study of organised beings, especially meet us at every turn.

“Truth we know must be self-consistent, nor can one truth contradict another, even though the two may have been arrived at by totally different processes—in the one case, suppose, obtained by sound scientific investigation; in the other case, taken on trust from duly authenticated witnesses. Misinterpretations, of course, there may be on the one side or on the other, causing apparent contradictions. Every mathematician knows that in his private work he will occasionally, by two different trains of reasoning, arrive at discordant conclusions. He is at once aware that there must be a slip somewhere, and sets himself to detect and correct it. When conclusions rest on probable evidence, the reconciling of apparent contradictions is not so simple and certain. It requires the exercise of a calm, unbiassed judgment, of looking at both sides of the question; and oftentimes we have long to suspend our decision, and seek for further evidence. None need fear the effect of scientific inquiry carried on in an honest, truth-loving, humble spirit, which makes us no less ready frankly to avow our ignorance of what we cannot explain than to accept conclusions based on sound evidence. The slow but sure path of induction is open to us. Let us frame hypotheses if we will; most useful are they when kept in their proper place, as stimulating inquiry. Let us seek to confront them with observation and experiment, thereby confirming or upsetting them as the result may prove; but let us beware of placing them prematurely in the rank of ascertained truths, and building further conclusions on them as if they were.

“When from the phenomena of life we pass on to those of mind, we enter a region still more profoundly mysterious. We can readily imagine that we may here be dealing with phenomena altogether transcending those of mere life, in some such way as those of life transcend, as I have endeavoured to infer, those of chemistry and molecular attractions, or as the laws of chemical affinity in their turn transcend those of mere mechanics. Science can be expected to do but little to aid us here, since the instrument of research is itself the object of investigation. It can but enlighten us as to the depth of our ignorance, and lead us to look to a higher aid for that which most nearly concerns our well-being.”

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 23th of last month I was called on to attend Mrs. K., aged thirty, who stated she was carrying her second child for about three months, and that three days previously she was suddenly seized with pain, and the passage of blood through the vagina. She said the pain was similar to that as if she were in labour, that it used to cease for a considerable time, and again reappear. She had passed (as I understood) a great deal of blood.

By auscultation I perceived that the foetus was living, having advanced to about the fourth month. On examination per vaginam, I found the uterus contracting, with the os dilated to the extent that I could almost introduce the top of my middle finger. I directed my attention to preventing expulsion, and with that object recommended perfect rest in the recumbent posture, with drinks and chicken broth, and prescribed a mixture (somewhat unchemical), composed of acetate of lead and opium, the latter in a large proportion, to be given at regular intervals. I also gave directions that in case the pain and hæmorrhage continued for any time, to send for me. The

woman progressed favourably, and is now perfectly recovered. There was no doubt but in this case premature labour had begun, and I think the case interesting, as showing how, though uterine action may have absolutely commenced, it is possible to overcome it by the aid of appropriate remedies, and that cases apparently hopeless may thereby be saved.

Yours truly,

RICHARD O'KELLY, L.R.C.S.E.

Cooleclevano Lodge, Kilmichael, Macroom, Aug. 9.

MUSTARD AND ITS VOLATILE OIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit us to trouble you with an inquiry which has suggested itself to us, after perusing the very valuable report upon mustard, contained in the *MEDICAL PRESS AND CIRCULAR* of the 4th of August?

At page 98 you state "Myrosine, a compound formed in the seeds, is an emulsion-like substance contained in the seeds of the black and white mustard, particularly in the latter, and is one of the most important ingredients. Myronic acid exists largely in the black seed but not in the white, it is present in the form of a potassium salt." You further state "myrosine and myronic acid react upon each other in the presence of water and produce sulphocyanate of allyl or the volatile oil of mustard, to which oil mustard owes its peculiar properties."

It would appear, therefore, that genuine mustard may vary in its chemical properties according to the proportions of flour used, from the black and white mustard seeds.

We therefore beg permission to inquire, if your analysts have decided in their minds, what are the best proportions for the flours of black and white mustard seeds to bear to each other in genuine mustard sold for table use?

Should you kindly favour us with a reply, we will make use of the information by henceforth mixing our genuine mustard in the proportions that you may suggest.

We remain, Sir,

Your faithful servants,

KEEN, ROBINSON, BELLVILLE & Co.

Garlick hill, London, E.C., August 21, 1869.

* * Myronic acid, which is present in the form of myronate of potassium in the black mustard seeds, is the source of the volatile oil of mustard, or sulphocyanate of allyl. White mustard seeds do not contain any myronic acid. Although a small quantity of an acrid oil peculiar to those seeds is generated on treating them with water; myrosin, an emulsion-like substance, is contained in both the white and black mustard seeds, particularly in the first. Ludwig and others have stated that myrosin is not essential to the formation of mustard oil from myronic acid; but, if not absolutely essential, it so wonderfully facilitates its formation, that for all practical purposes its presence may be considered necessary. As the black seeds contain both myrosin and myronic acid, they generate the essential oil on being treated with water. The largest amount of essential oil that has been procured from the black seeds seems to be 10 parts from 1,000; but as the addition of a small quantity of white seeds (which do not contain myronic acid, the source of the oil) does not diminish the percentage of oil; it would seem that the myrosin is hardly present in sufficient quantity in the black seeds to determine the decomposition. The quantity of white mustard seed desirable should not, in our opinion, exceed one-third of the entire weight; but we believe that the quantity used is far above that proportion. This is done for economy, the mustard flour from the white, of course, being much cheaper than that procured from the black. There is no doubt that there can be two mustards by different makers having the same amount of wheat flour present, and yet they shall vary very much in the amount of pungency when mixed. Another of our correspondents inquires as to the mode adopted for removing the fixed oil before dressing. We cannot give any information on this point; it was made on good authority, and is borne out by the discrepancy found in the amount of fixed oil present in different samples of mustard. We do not think, however, from further inquiries, that the practice is very general. We believe that a mustard farina is prepared in France which is perfectly free from the fixed oil. It is used for blistering purposes.

Gleanings in Medicine, Surgery, and the Allied Sciences.

SPECTRUM ANALYSIS.

THE *Contemporary Review* for the current month has the following article, which will just now be interesting:—

So early as in 1814, Fraunhofer examined the spectra of certain stars, and he found therein a general though not an absolute resemblance to the spectrum of sunlight. Unable himself to read the wonderful lessons contained in the dark lines which interrupt the continuity of their light, it was reserved for our countrymen, Messrs. Huggins and Miller, to state with confidence that the stars, like the sun, are incandescent bodies, each surrounded by an atmosphere containing many of our terrestrial metals in the state of glowing vapours. Mr. Huggins has also shown that many of the nebulae certainly contain vaporous aggregations of hydrogen, nitrogen, and some other gaseous substance not as yet identified with any known terrestrial element, and all of them in a state of intense incandescence. The same patient and sagacious philosopher has detected hydrogen in the nucleus of several comets, and unmistakable traces of carbon in two of these mysterious bodies; he has thus added another link to the chain of evidence which connects the comets with certain rings of meteoric matter circulating round the sun. Finally, all these marvellous and unexpected phenomena, which have flashed as it were into the human cognizance within the last seven or eight years, go far to establish the truth of Laplace's hypothesis, that the whole visible material universe is an evolution of things, arising from the condensation of vast tracts of gaseous or vaporous matter scattered through the regions of space.

But the most extraordinary revelations made by the application of the spectroscope are those which have been still more recently brought to light regarding the vast plutonic operations which are now proceeding, and which, without any great exaggeration, may be said to be even visible on our sun. It is no doubt known to the majority of our readers, that when the sun is completely concealed by the dark body of the moon during a total solar eclipse, certain luminous protuberances, varied in form and extent, become visible even to the naked eye, some of which extend to the enormous distance of from twenty to eighty thousand miles from the general photosphere. At the recent solar eclipse of 1868, expeditions were despatched by the various European Governments to examine the nature of these strange flames by the infallible methods of the new Spectrum Analysis. It was at once discovered that the chief ingredient in these rose-coloured protuberances was hydrogen; but, in addition to this, Mr. Janssen in India, and Mr. Lockyer in England, each independently of the other, discovered that the traces, or rather the spectra, of these rose-coloured flames could be observed at all times in the bright sun *without the intervention of an eclipse*. Mr. Huggins so far improved the method as to render the entire forms of these flaming protuberances visible when the sun shines in a clear atmosphere.

Hence the well-instructed eye may now behold the amazing spectacles of jets of glowing hydrogen gas shooting (and almost waving about) for thousands of miles beyond the body of the sun, out of the incandescent vaporous atmosphere of metals which surrounds it.

It is thus from an astronomical, or, as we may properly call it, a cosmical, rather than from a chemical point of view, that the results of the new process appear the most astonishing, and possess the greatest promise for the future. To the philosophical astronomer the prism has become the necessary supplement of the telescope. The province of the telescope lies in the determination of the forms and positions of the vast and remote bodies which constitute the visible universe; that of the prism lies in the unhelped-for analysis of their material composition. It has already made us acquainted with certain envelopes of glowing metallic vapours which constitute the atmosphere of the sun, and especially of that envelope of hydrogen which overtops them all, and from which torrents of the heated gas are seen to surge forth in fantastic changing forms for tens of thousands of miles; it has already demonstrated the identity of stars with suns; and in nebulae and comets it has detected the existence of vaporous material the same as those which to the chemist are the most familiar of terrestrial elements.

These are scientific achievements without a parallel in the annals of the progress of knowledge, but we are persuaded that a more remarkable and still more important future is in reserve for the new process. The very recent researches of MM. Frankland, Huggins, and Lecky, afford some happy indications that from Spectrum Analysis we may be able to determine the amount of heat and of molecular condensation in the vaporous envelopes of the sun, and in the materials which form the nebulae. If this should prove to be the case, then, in process of time, it will be possible to detect the progress of any changes which may occur in the sun or the nebulae with respect to the temperatures of both, and in the aggregation of the materials of the latter. Herein we discern one of the great features of the astronomy of the future.

We may confidently hope that the prism will determine such mooted questions as the periodic variation of temperature or the slow secular cooling of the sun and its envelopes, as well as any growing condensation of nebulous matter into suns and planets, and will ascertain the motions of recessions or approach of the remoter denizens of the universe towards our earth. It may even give the inhabitants of this earth some effective and intelligible warning that their great material system of existence is on the wane.

THE DECOLOURIZATION OF TINCTURE OF IODINE.

As much has lately been said and written on this subject, it may not be uninteresting to add a suggestion or two to the store of knowledge already communicated. The methods proposed are so familiar to all, having been fully discussed in late periodicals, that I need do no more than mention them; yet, in my opinion, they do not really give us what we desire. The process by the action of carbolic acid and glycerine has its disadvantages, in being somewhat uncertain, and requiring more time for its successful completion than is desirable; the other process, by the addition of hyposulphite of soda, although undoubtedly hastening the action, in many cases causes a deposit of metallic iodine. The ordinary soap liniment seems to me to accomplish what we wish to attain better than either of these processes. True, it does not actually decolourise the iodine, yet it possesses the great advantage of enabling us to rub it freely into the skin, without the characteristic colour of iodine being imparted to it; and thus we can use iodine as an external application where the antipathies or caprice of patients would otherwise present a formidable barrier to its use, were it employed in the ordinary way. As a liniment, one part of tincture of iodine, one of glycerine, and two of soap liniment, may be used for a long time without producing much cutaneous irritation, or any characteristic decolourization. Stains caused by the accidental application of tincture of iodine may be at once removed by the use of soap liniment.—*California Medical Gazette.*

Medical News.

DR. WILSON FOX has been gazetted Physician Extraordinary to the Queen. We congratulate the young Professor of Medicine at University College on so early obtaining a Court appointment, and hope it may not divert him from the steady scientific work he has been doing. Many older men will say he has indeed been "a lucky fellow." The appointment is one that certainly places at the service of Her Majesty an able young physician.

MR. ERASMUS WILSON has been elected to the Professorship of Dermatology, which he so munificently founded. The *Lancet*, which has never let slip the opportunity of a spiteful sentence about this gentleman, has the impudence to advise him to "devote his lectures to professional, and not to personal details." If the *Lancet* would take the advice thus impertinently offered by one of its own scribes, how much better would it be for the profession, which is constantly outraged by the rancour so freely exhibited in its pages!

UNIVERSITY OF EDINBURGH.—The following is a list of the gentlemen on whom degrees in Medicine were conferred at the Graduates' Cereimonial, of which a description has already appeared in the MEDICAL PRESS AND CIRCULAR. [*** Those who have obtained prizes for their dissertations. ** Deemed worthy of competing for the dissertation prizes. * Commended for their dissertations.]—Candidates who received the Degree of Doctor of Medicine under the New Statutes:—*James Ormiston Affleck, Scotland, M.B. and C.M.; David Hawley Burn Anderson, Scotland, M.B. and C.M.; John Francis Vincent Bent, England, M.B. and C.M.; Charles Moss Campbell, India, M.B. and C.M.; Henri Louis Colladon (M.A. Geneva), M.B. and C.M.; ***John Haddon, Scotland,

M.B. and C.M.; Alexander Richardson Haughey, Ireland, M.B.; Charles Holden, New Brunswick, M.B. and C.M.; George Hunter, Scotland, M.B. and C.M.; William Brown Hunter, Ireland, M.B. and C.M.; John Kirkwood, Scotland, M.B. and C.M.; **Robert Lightfoot, England, M.B. and C.M.; George May Low, England, M.B. and C.M.; John Macbeth (M.A. Edin.), Scotland, M.B. and C.M.; Alexander Dall Macdonald, Scotland, M.B. and C.M.; John MacRae, Scotland, M.B. and C.M.; Edward Malins, England, M.B. and C.M.; William Munro, Scotland, M.B. and C.M.; Henry Alleyne Nicholson, England (D. Sc. Edin.), M.B. and C.M.; Alfred Pullar, Scotland, M.B. and C.M.; James Ramsay (M.A. St. And.), Scotland, M.B. and C.M.; *Christopher Currie Ritchie, Scotland, M.B. and C.M.; Alexander Steven, Scotland, M.B. and C.M.; Henry Stolterfoth (M.A. Cantab.), England, M.B. and C.M. (received the Degree of M.D. on 31st October, 1868); James Call Weddell, Berwick-upon-Tweed, M.B. and C.M.; Henry Carter Wigg, Australia, M.B. Candidates who received the Degree of Doctor of Medicine under the Old Statutes:—Alexander Grant, (M.A. Aberd.), Scotland; Donald Ross, Scotland; Thomas Appleby Stephenson, England; *** John Miller Strachan, England; William Josiah Walker, England. Candidates who received the Degrees of Bachelor of Medicine and Master in Surgery. [† Indicates that the candidate has passed the examinations with First-class Honours. ‡ Indicates that the candidate has passed the examinations with Second-class Honours.]—† George Amsden, England; Matthew L. Bartholomeusz, Ceylon; Alexander Henderson Begg, Scotland; Alexander Bennett, Scotland; Thomas Marshall Bennett, England; George Keith Brebner, Scotland; William Macfie Campbell, Scotland; William Jackson Cleaver, England; Henry David Cook, India; Francis Pritchard Davies, Wales; John Ewart, England; John Charles Hirschfeld, Isle of Man; Alfred Hollis, Isle of Wight; Charles John Krickenbeck, Ceylon; Alfred Robert Law, England; George Lorimer, (M.A. Ed.), Scotland; Gilbert P. Mackenzie, British Guiana; Henry Miller, England; Robert Moodie, Scotland; Aeneas Munro, Scotland; William John Naismith, India; Francis Cobham Nicholson, Melbourne, Australia; ‡ George Kincaird, Scotland; Orlando Reeves Pranker, England; Urban Pritchard, England; Adam Scott Reid, Scotland; David William Roberts, Wales; John Allan Robertson, Scotland; Thomas Sayer, England; William Gifford Scott, India; Alexander James Sinclair, Scotland, (received the Degrees of M.B. and C.M. on 31st October, 1868); Robert Mitchell H. Smith, Scotland; Edward Smyth, Scotland; Charles Stewart, Scotland; Alfred Thomas, England; Edwin Thompson, England; James Archer Thomson, England; George Waugh, Scotland; John Manuk Zorab, India. Candidates who received the Degree of Bachelor of Medicine:—Byrom Bramwell, England; Thomas Dodson Chalmers, England; Thomas Kay Gray, Scotland; Andrea Carlo Francisco Rabagliati, (M.A. Edin.), Scotland; George Ballingall Stuart, India.

NOTICES TO CORRESPONDENTS.

IN all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

DR. G. M. DICKENSON will please receive our best thanks.

DR. T. MORE MADSEN.—We are waiting the return of your proofs. One slip only of the three sent you has as yet come to hand.

DR. JACKMAN, Swynbridge.—Reforms in the direction you speak of have been so often promised, that we almost despair of any very comprehensive scheme. The matter may be brought forward next Session.

COMMUNICATIONS, Enclosures, &c., received from Dr. Balthazar Foster, Birmingham; Dr. Purdon, Belfast; Mr. Wallace Robertson, Glasgow; Dr. Tidy, Hackney; Dr. Drysdale; Dr. Gordon, Portsmouth; Dr. Waring-Curran, Sutton; Dr. Sabben, Stoke Newington; Mr. Gamble, Liverpool; Mr. Barker, London; Mr. Bower; Dr. Aspray, London; Dr. Hunt; Mr. W. E. Benson, Liverpool; Mr. G. Woodhall, Leeds; Mr. Eskell; Mr. Messent; Mr. W. Ludlow Roots, Kingston; Mr. G. M. Dickenson, Pailton; Mr. G. Pink, Eastmeon; Dr. Price, Holyhead; Mr. Belville; Dr. Maenamara, Exeter; Dr. Birehennell, Macclesfield; Dr. Fletcher, Dublin; Dr. Leary, Portsmouth; Dr. Burder, Bristol; Dr. Crawford, York; Mr. W. H. Colbourne, Chippenham; Dr. Johnstone, Brampton; Mr. W. S. Whatford, Brighton; Mr. Vincent, Liverpool; Dr. Clement, M.P., Shrewsbury; Dr. T. More Madden, Dublin; Dr. J. H. Jackman, Swynbridge; Mr. Craine, Ramsey.

VACANCIES.

Royal General Dispensary.—Physician. Salary £40. Election September 2.

Warneford Hospital, Leamington.—House-Surgeon. Salary £100.

Eastbourne Union.—Medical Officer. Salary £90, with extra fees.

Royal Maternity Charity.—Physician. Applications on or before the 28th inst. See advertisement.

Lecture.

ON THE USE OF THE FORCEPS IN MIDWIFERY PRACTICE.

DELIVERED IN THE

ROTUNDO DUBLIN LYING-IN HOSPITAL.

By THOMAS MORE MADDEN, M.R.I.A.,
Assistant Physician to the Hospital.

LECTURE I.

GENTLEMEN,—There is no question connected with the study of midwifery of greater practical importance than the best manner of assisting women in child-birth, so as to accomplish the delivery of a living child from a living mother, with safety to both, in cases which must have terminated unfavourably to either if nature were not aided by art. There are but two instrumental operations recognized in English midwifery practice for this purpose, although in other countries other operations are successfully resorted to with the same intention.

The operations to which I have referred, as recognized in this country, are the applications of the vectis and forceps. The former is now seldom resorted to, at least in the practice of this, the largest and oldest Lying-in Hospital in the United Kingdom; and I shall, therefore, confine my observations this evening to the latter.

The subject of this Lecture is one well deserving your most careful consideration, for your success in midwifery practice, and, what is of much greater importance, the well-being of your patients, will be materially influenced by your forming sound views on the use of the midwifery forceps, and on your being able to carry those views into practice with promptitude and dexterity when the occasion arises.

Notwithstanding all that has been written on this sub-

ject of late years, the application of the forceps is still, I fear, regarded with prejudice by many practitioners; and in some of the text-books on midwifery which are in vogue with students, the employment of the forceps is restricted by the reiteration of rules prescribed by writers whose own experience of the use of this instrument was extremely limited, and who attributed disastrous results to the forceps, which were probably caused by their want of dexterity in its application, or by their delay in resorting to it. I should be very reluctant, however, to advocate the habitual use of the forceps in ordinary cases, for I thoroughly agree with Dr. Blundell that "meddlesome midwifery is bad midwifery;" and I think it is obvious that the course of natural labour should never be interfered with except for the purpose of saving either the parturient woman or the child from some danger which would probably result to either from the protraction of the labour. But, even with this limitation, I think the forceps may be much more frequently used in midwifery practice than it generally is.

The term "meddlesome midwifery" cannot be properly applied to any operative interference that may be necessary in a case of labour for the purpose of saving either the mother or the child from any danger, or, the former only, from the sufferings of over-protracted childbirth. The latter consideration is not, as I think, sufficiently attended to by some very eminent authorities on this subject, and I am therefore anxious to impress on you in the course of these lectures the propriety of employing the forceps more frequently than is usually advised for the purpose, in certain cases, of shortening the sufferings of tedious labour, and thus, at the same time, also obviating its dangers.

The history of the introduction of the forceps into obstetric practice is a subject of the highest interest, and I only regret that the scope of these lectures does not allow me now to enter on it as I should wish to do. I would, however, strongly recommend any of you who take an interest in tracing the progress of our art from its infancy to its present degree of perfection to read for yourselves on this topic the introduction to Smellie's "Midwifery," published in 1752; Dr. J. Davis's "Operative Mid-

wifery;" and Dr. Churchill's "Researches on Operative Midwifery;" in which you will find this subject fully discussed.

None of the ancient Greek or Roman medical writers allude to the forceps as a means of delivering living children with; but an instrument very similar to our modern forceps was found some years ago in the house of an obstetrix in the excavations at Pompeii. (a) The Arabians appear to have been acquainted with this method of assisting Nature in cases of difficult labour, and Avicenna refers distinctly to the forceps for this purpose. The instrument, however, appears to have passed into disuse, and to have been completely forgotten by all writers and practitioners of midwifery from the time of Avicenna until that of Jacobus Ruffe, who, in his work on "Human Conception and Generation," published at Zurich in 1554, speaks of a forceps without teeth—"forceps qua dentes eruuntur"—for the purpose of delivering living children with—"ut si possibile sit, id quod protrahendum est educat facilliter." Nothing, however, seems to have come of Ruffe's suggestion till the elder Chamberlen constructed and employed the forceps, of which you have facsimiles on the table before you, about the year 1647. These forceps were confined by the Chamberlen family to their own practice; nor do they deserve much credit for an invention which they only employed for their own aggrandisement. No description of the forceps was given to the profession till Mr. Chapman, in 1733 published an account and engraving of Chamberlen's forceps, which he had received from another practitioner who had used them for several years previously. Thus it was to Chapman, and not to any of the Chamberlen family, that the credit of introducing the midwifery forceps into practice is due. Three distinct forms of Chamberlen forceps are on the table before you, and it is enough to say that they differ from the short forceps now in use very little, excepting the formation of the lock, which, in Chamberlen's second forceps, is similar to that of the modern French forceps, and the thickness and clumsiness of the blades. From the Chamberlens' time to the present day innumerable have been the attempts to improve the forceps, and I now exhibit to you a vast number of these instruments, in which you will see much evidence of the absurdities of misapplied ingenuity.

The worst of these forceps is that generally used in France, and which is recommended by some American writers. It is a horribly clumsy misshapen mass of iron, sixteen inches in length, and locked with a pivot-and-mortice lock, very difficult to adjust. I need not waste time in pointing out the objections to this instrument, which are obvious.

Some years ago the forceps was hardly ever resorted to until the parturient woman, worn out by the protracted sufferings she had endured, was almost moribund, and when, too, the child was probably dead, in consequence of the long-continued pressure it had been subjected to. And yet, as I could show you by a reference to the statistics of this Hospital, in forceps cases the mortality to the mother is always less in proportion to the frequency of the operation, as well as to its early performance in those cases which require it.

In order to understand why it was the forceps were so little used in this Hospital at the time I refer to, we must bear in mind the rules laid down and acted on by the most eminent obstetricians for many years. Dr. Osborne says that, "in the state indicating the use of the forceps, all the powers of life are exhausted, all capacity for further exertion is at an end, and the mind as much depressed as the body; they would both together sink under the influence of such continued and unavailing struggles." (b) Dr. Denman enjoins us to wait for at least six hours, with the head of the child stationary in a position favourable for the use of the forceps, before the instrument should be applied; (c) Dr.

Merriman confirms this rule; (a) Dr. Gooch extended this period of suffering and danger to twelve hours; (b) and Dr. Collins did not think it right to interfere "as long as the head advances ever so slowly, unless the child be dead," or unless some urgent symptom presented itself. (c) When such rules were acted on, can it be wondered at that the forceps should fail to deliver "a living child from a living mother?"

In the statistical reports of the successive Masters of the Dublin Lying-in Hospital we find evidence of the fallaciousness of the rules I have just quoted, and of the advantage which has followed their non-observance. Thus, in Dr. Joseph Clarke's Mastership, from 1787 to 1793, during which 10,387 deliveries took place in the Hospital, the forceps were only used fourteen times; two of the mothers were lost, and the result to the children is not recorded. And in his private practice, extending over a period of forty years, during which time he attended 3,878 cases of labour, Dr. Clarke only once attempted to apply the forceps, and then did not succeed. (d)

In Dr. Labatt's Mastership, from 1815 to 1821, during which time there were 21,867 births in the Hospital, the forceps were never applied. In Dr. Collins's Mastership, from 1826 to 1833, the number of births in the Hospital was 16,654, and only in 24 of these cases was the forceps used, while craniotomy was performed in no less than 118 cases. I have generally observed that those accoucheurs who employ the forceps most frequently use the perforator most rarely. Drs. McClintock and Hardy, in their Report of three years' practice in the Hospital, under the Mastership of the late Dr. Charles Johnson, from 1842 to 1845, state that in 6,702 deliveries the forceps was only used in 18 cases, in 16 the vectis, in 30 ergot of rye was given, and in no less than 52 cases the perforator and crotchet were resorted to. (e)

To the present Master of the Hospital the great credit is, I think, due of having, when Assistant Physician, been the first to advocate and introduce into the practice of this Hospital the early and frequent use of the forceps in cases of difficult labour. In the Report which he edited, conjointly with Dr. Sinclair, of the practice of the Rotundo Hospital during Dr. Shackleton's Mastership, from 1847 to 1854, in 13,748 cases Dr. Johnston tells us that no less than 226 deliveries were accomplished with the forceps. (f)

Dr. Halahan, in his account of the forceps cases which occurred in his term of office as Assistant Physician, during Dr. McClintock's Mastership, tells us that the forceps was used fifty-six times, or about once in every sixty cases. (g)

In private practice the operation in question, even a few years ago, was even more rarely resorted to than it was in the Hospital. Thus, Dr. Davis (senior) says that, in his opinion, it cannot be absolutely necessary to have recourse to the forceps or lever more frequently than once in 300, or, at most, in 250 cases. (h) And Dr. Davis (junior), improving on this rule, only used the forceps seven times in 7,371 deliveries—that is, once in every 1,053 labours. (i)

Dr. Churchill's statistics, published in the last edition of his "Theory and Practice of Midwifery," shows a great increase in the number of forceps operations in British practice within the last twenty-five years. Thus, in the tables published in Dr. Churchill's "Researches on Operative Midwifery," in 1841, it is stated that in Great Britain out of 42,196 cases of labour, there were 120 forceps cases, or about 1 in 351; while in France the proportion was 1 in 162, and in Germany 1 in 153. (j) But in the same

author's work, published in 1866, we learn that the proportion of forceps cases in British practice has risen to 1 in 171, while in France it is now 1 in 140, and in Germany 1 in 106. (a)

In British midwifery practice, where the operation is less frequently performed than it is abroad, the results of the operation are not so satisfactory as they are in France and Germany. In the former, Dr. Churchill shows that 1 in 29 of the mothers, and 1 in 5 of the children, were lost; while in the latter the mortality of the mothers is only 1 in 35, while that of the children remains about the same. In private practice the mortality is much less, however, than in the foregoing cases of forceps operations which occurred in the practice of large public institutions, only 3 mothers and 68 children having been lost in 577 forceps cases in private practice. Dr. Churchill, in 99 forceps cases, only lost two of the mothers, and both died of puerperal fever which prevailed at the time. (b) Dr. John Beatty used the forceps in no less than 111 cases with the most perfect success, and did not lose a single patient by it. (c)

In Dr. T. Beatty's memoir on the forceps, published in the *Dublin Medical Journal*, vol. xxi., we find that in all the cases he operated on—15 in number, "the operation was performed with complete success, as far as the mother was concerned;" seven of the children were born alive and eight dead; "but of these six were born under circumstances that would have caused a similar result independently of the operation. Since that paper was published—from 1842 to 1866—Dr. Beatty tells us he had recourse to the forceps thirty-five times in his private practice. Many of these forceps cases were first labour, and in twenty-eight cases the children were delivered alive; the other seven were dead." (d)

I have myself applied the forceps in 38 cases. In only one of these was the child born dead, and there was evidence of its death before the forceps was applied. Two of the mothers died, but one was moribund from puerperal convulsions when the operation was performed, so that in reality in only one case could the patient's death have been by any possibility ascribed to the application of the forceps, and in that one case the woman had been for many months before her confinement a patient of mine, suffering from dropsy and albuminuria, and after death the kidneys were found extensively diseased.

So much for the statistics of this operation, and dry as these figures must, I fear, seem, yet I venture to think that at any rate what has been just said will be of great service if it only impresses on your mind the fact that the application of the forceps is, *per se*, a comparatively safe operation, both to the mother and child. Thus, in forceps cases, even under unfavourable circumstances, only one in thirty-four of the mothers is lost, whilst in craniotomy cases, not only are all the children destroyed, but, moreover, one in every five of the mothers is lost.

The midwifery forceps is a tractor, a compressor, and a lever of the first order, the fulcrum of each blade resting in the handle of the opposite blade. There are two principal varieties of forceps—namely, the long and the short forceps. The latter are generally employed in ordinary cases, and I shall first describe the instrument which I prefer myself, and point out its uses and mode of application.

The forceps I employ differs in several respects from the short forceps generally used, and has been made by Mr. White, of Sackville street, in accordance with my directions. The measurements of this forceps are as follows: Length of instrument, $10\frac{1}{2}$ inches; length of blades, $6\frac{1}{2}$ inches; length of handle, including lock, 4 inches; widest space between blades when locked, $2\frac{7}{8}$ inches; interval between points, $1\frac{1}{4}$ inches. The curve of the blades

is very gradual, and commences half-an-inch above the lock, the space between which and the commencement of the curve of the blades is bevelled internally, and bent slightly outwards to form a space for the finger of the operator. The blades are only one inch and a third at their widest point, and which is just three inches and-a-half from lock. They are tapered very gradually to and from this point, and are fenestrated as nearly as possible throughout their entire length, and as thin as is consistent with strength. Special care has been paid by Mr. White to the avoidance of any sharp edges or points. The handles are checker-worked in the old fashion, and the total weight of the instrument is only eight ounces and a quarter.

The modifications introduced into the construction of this forceps, trivial as they may appear separately, are, I venture to think, of advantage in facilitating the application and use of the instrument. The fenestra being very wide in proportion to the width of the blades, the rims of the fenestra are much thinner than is usual, so that when the forceps is applied to the head, the protuberances of the parietal bones projecting through the fenestra almost completely project over and conceal the rims, so that there is less probability of the maternal structures being injured during the extraction, being in closer contact with the child's head than is the case when the ordinary forceps are used.

My chief dependance on the forceps is as a simple tractor rather than as a lever or compressor. The ring between the locks, into which the forefinger of the right hand is introduced during extraction with my forceps, will be found of material aid to the operator, and I generally rely mainly on this, and seldom find it necessary to use any degree of power with the handles.

This forceps, moreover, fits the fetal head closer than any forceps I have used, and is, therefore, less liable to slip, being so curved that the blades are in close apposition with the head throughout their entire length, and exercise an equal degree of pressure on every part of it with which they are in contact. In some of the modern forceps on the table you observe that the blades are so sharply curved that the instrument is in contact with the head at two points only, on which, therefore, an injurious degree of pressure must of necessity be made.

The shortness of the handles makes the application of the forceps much more facile to the operator, and the instrument is, of course, more easily carried, occupying less space than Beatty's, Churchill's, or any other short forceps commonly used, and can be more readily slipped on without making an unnecessary parade of your instruments before the patient's friends, although you should never, if possible, apply the forceps without a consultation, nor without apprising the patient that you are about to assist her.

Pressure on the child's head beyond a safe limit is guarded against by the lesser strength of the blades and shanks of this forceps, which only admits of a limited degree of compressing power being used.

The compressing power of the forceps is generally supposed to be very limited, and the experiments of Baudelouque are generally quoted as being conclusive on this point. This eminent obstetrician performed nine experiments on the heads of still-born children with Levret's forceps. In one case the instrument bent in reducing the head only two lines; in the next the sutures were torn, and the brain escaped by compressing the head three lines; in two cases in which the sutures were loose, he reduced the head four lines, and another case four lines and-a-half; in the seventh experiment three lines; and in the eighth, two lines of space were gained. (a)

These experiments, however, do not appear to me to justify the opinion as to "the limited power of the forceps when used as a compressing instrument," (b) which Dr. Murphy and other recent writers join with Baude-

logue in expressing. By Baudeloque's own showing, he was able to compress the foetal as much as half an inch in three out of nine cases, and, as was long since pointed out by Dr. Rigby,* the pressure which is gradually employed by the forceps properly applied to the head of the living child, the plastic properties of which are so vast, will produce very different results from the violent and sudden force applied by Baudeloque to inanimate structures.

We now proceed to consider in what cases the instrument I have just described may be employed. These cases we will consider one by one, but before doing so I shall point out the general principles on which we act in applying the forceps. This instrument is indicated in cases of natural presentation, in which any danger from delay in the second stage of labour either exists, or is threatened to the mother or to the child. In other words, the forceps may be applied in such cases whenever there is a well-founded conviction that without assistance the labour will not terminate favourably for the mother or child, not only with regard to the safety of the lives of either, but also with regard to the safety of the organs, which in either would be injured by the labour being further protracted.

(To be continued.)

Original Communications.

SEQUELÆ OF OTITIS.

By J. BIRCHENALL, M.R.C.S., Macclesfield.

Mrs. B., aged fifty-four, previously in tolerable health, was seized in the early part of December, 1846, with acute otitis, which yielded after a time to leeching, blistering, &c. As the weather was variable and cold, she kept her room during her first week of convalescence; but on Christmas day, contrary to my instructions, came down into the dining-room and sat with the family to dinner. Among other things she partook of roasted goose, was sick in the course of the day, complained of chilliness, and went early to bed.

On my visit next morning, I found her again suffering from acute pain in the ear, with a return of febrile symptoms. In this instance the complaint did not yield to the previous treatment, nor yet to a course of calomel and opium.

The symptoms gradually assumed a grave and unpromising aspect: there was insomnia, with a highly excited expression of countenance; great restlessness and delirium; incoherent chattering; angry crimination and scolding of her attendants: all this was followed by the frequent utterance of very obscene language, and the most profane execrations of both her husband and his two daughters by a former wife—two amiable young ladies, to whom she had always been greatly attached. On the sixth or seventh day the frenzied excitement was succeeded by a faint muttering; there were rigors, followed by constant jactitation of the lower extremities; the body rigidly maintaining the supine posture; and death supervened on the tenth day of the relapse.

The *post-mortem* revealed a reddened and highly injected condition of the arachnoid and pia mater, over the entire cerebral surface. There was some effusion into the ventricles, and pus at the base of the skull, behind the os petrosum on the side affected, which was also diffused over the lower surface of the cerebral hemisphere. The spinal column was not exposed, as I had to prosecute the investigation alone, by the express desire of the family.

I may observe, that my patient had always maintained a virtuous demeanour; had been piously disposed from early life; and was, up to the period of her death, an accredited and estimable member of a Christian church.

* Dr. Rigby, "Midwifery," p. 162.

The case is interesting psychologically, as indicating how closely our mental and moral affinities are allied; and, in a medico-legal point of view, the well-defined succession of the latter class of phenomena points to the conclusion that moral insanity is dependent upon antecedent intellectual derangement; consequently, that outrages and crimes which are the result of violently excited moral sentiments are not to be regarded as the acts of an irresponsible agent unless they have been preceded by morbid mental associations.

COMPLETE ABSENCE OF ANUS WITH RECTUM OPENING INTO VAGINA.

By Dr. GARLAND, Newry.

ON July 27th, 1869, Mrs. — brought for my advice a female child, æt. three months, suffering from imperforate anus. On examination, I found that the obstruction was not of the membranous form, but that the rectum for a considerable distance was blocked up with a dense mass of fibro-cellular structure, and communicated with the vagina, through which the contents of the bowel escaped. I advised an operation as the only alternative for a speedy fatal issue, or at best a brief but miserable existence. The mother consented, and I had the satisfaction of assisting Dr. Morrison, of this town, who, by cutting down on the point of a bent probe, introduced into the *cul de sac* of the rectum through the vagina, opened the gut at the depth of about two inches from the surface; thus making an artificial anus with a moderate amount of hæmorrhage. I need scarcely say that the operation was performed with that skill and dexterity which Dr. Morrison is well known to possess.

Finally, a conical plug was inserted in the rectum, and the mother instructed as regards its manipulation. The case has gone on most satisfactorily from the beginning up to a recent date. The fæces are passing through the natural channel, while the abnormal opening in the vagina seems to be rapidly closing.

Mr. Erichsen takes a gloomy view of these cases of *complete absence of anus*, and says, "It commonly happens that death results in a few days from irritation occasioned by the absorption of the excreted fluids."

I think this case is worthy of record and should encourage others to operate as the *dernier r essort* under similar circumstances.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.

JERVIS STREET HOSPITAL.

Blood Poisoning and Inflammation of Lymphatics. Tonic Treatment.

Under the care of Mr. STAPLETON.

(From the Notes of Mr. MULLIGAN, Resident Pupil.)

PATRICK C., æt. eighteen, a labourer, of slight muscular habit, occupied in attending cattle, was admitted into Jervis Street Hospital, May 2nd, 1869, suffering from diffuse inflammation of an erysipelatous character, spreading over the right side of his face.

At the time of his admission he was in a weak feverish condition, with much constitutional disturbance; his tongue was dry and furred; his pulse rapid and weak; his respirations frequent; his voice indistinct; and his speech impaired. The lower lip was enlarged and

prominent, and of a deep purple colour. The next morning the upper lip became also enlarged. A small pimple was detected on the lower lip. There was great effusion about the eye of the affected side. The superficial lymphatics were inflamed, streaks of a bright red colour being visible, corresponding to their situation in different parts of the body. On passing the finger into the mouth, the cheek was found to be enormously thickened, and at first the mass was supposed to have opened into the mouth, owing to a deceptive condition caused by the portion of the cheek where the opening of Steno's duct tied it down, not swelling like the surrounding parts, and simulating to the touch the character of a considerable opening into the tumefied cheek.

No history of purulent infection could be obtained; but he stated that on Sunday, about a week previous to his admission, he noticed a small sore pimple beneath the lower lip, which on the next day became more painful and irritable. He then suffered from nausea and headache, and was troubled with an uneasy warm sensation in the right side of his face. He went to work on Tuesday, but the pain and swelling increased so much, that on Wednesday he was obliged to keep his bed, and finally, finding himself getting worse, he came into hospital on Sunday.

On the day of his admission he was seen by Mr. Stapleton, who ordered him a mixture containing chlorate of potass and bark, and his throat being sore, a gargle containing the tinctures of myrrh and bark, and chlorate of potass.

For some days the side of his face continued to increase in size, the same medicines were continued, and a sulphate of iron lotion was kept constantly applied to the affected part. The upper eyelid being much swollen by serous effusion was scarified, and, together with the cheek—which remained very tender—was poulticed and fomented. His condition did not improve; he was feverish, suffered from severe rigors; his respiration was hurried; his pulse quick and weak; he passed restless nights; sweating profusely. Bed sores began to form in different parts of his body.

Being in this condition, Mr. Stapleton gave him large quantities of nourishment, he got as much as eighteen eggs and several pints of rich egg-flip in the day, and under this dietetic treatment he rapidly improved; the shiverings ceased; the pulse went down; the skin resumed its natural temperature; his voice got stronger; and the swelling and tenderness about his face became less. He continued to mend until May the 22nd, when unfavourable symptoms were again noticed; his pulse rose from 75 to 100; his tongue was covered with a brown fur; the shiverings and perspirations returned; he was drowsy and heavy during the day, and restless and wakeful during the night, he was ordered the bark and chlorate of potass as before. Some swelling remained still over the right eye.

May 24th.—Pulse 120; tongue covered with fur; coagulated blood passed from the nose. The night sweats continuing, he was ordered twenty grains of muriate of quinine in half an ounce of muriated tincture of iron—twenty drops every sixth hour.

He now began gradually to mend, and on the 6th of June was sufficiently well to leave for extern treatment, and change of air. About fourteen days after his discharge he was seen by Mr. Stapleton, who opened a large abscess, which had formed near the great trochanter.

On the 4th of August he was readmitted, the enlargement over the eye remaining. A few days after his reception, he had a fit of an epileptic nature. The tumour on the forehead was opened on the 11th August, and the frontal bone underneath found to be in a state of necrosis. Some matter made its escape, and a portion of necrosed bone was removed. Mr. Stapleton directed that he should get a mixture containing iodide of potassium and liquor potassæ with bark.

He is still in hospital, but is rapidly convalescing, the wound over the right eye progressing favourably, and no ill symptoms showing themselves.

Transactions of Societies.

THE PHARMACEUTICAL CONFERENCE.

THE Sixth Annual Conference has been held at Exeter.

Professor ATFIELD read the annual report, congratulating the members on the continued prosperity of the Society. At the last annual meeting the number of the members amounted to 562, and at the time the report was written they numbered 620, and by those just elected their numbers must be increased to 670 or 680. (Applause.) The income was also in excess of the expenditure by about £80. (Renewed applause.) The question had been debated by the Committee during the past year whether they should or not issue a year book or annual report on the progress of Pharmacy, and a sub-committee had been appointed to consider the question in all its details, and that Committee reported that they considered that a subscription of 5s. a-year would be sufficient to cover the cost of the publication. The Treasurer's (Dr. Brady's) report showed a balance in hand in August 1868, of £35 15s. 7d., £123 15s. had been received in members' subscriptions. The expenses included the cost of printing the proceedings, £24 10s.; contributions towards the expenses of the Norwich Meeting, £25; and some smaller items, leaving a balance in hand of £79 10s. 1d. The Treasurer announced that he estimated the amount of the subscriptions now due at £91 15s. The reports were unanimously received and adopted, and the members passed a hearty vote of thanks to the Secretaries and the Treasurer, for the manner in which they had conducted the business of the Society.

The PRESIDENT, after announcing that deputations from various chemists' associations in the country were present, delivered the inaugural address, observing that their sixth anniversary brought them to Exeter to find there a welcome no less cordial and fraternal than they had experienced on many previous occasions. The President then passed in review the events of the year in connection with Pharmacy, observing that the Pharmacy Act had come into operation since they last met, and in London they had found very little difficulty in complying with its provisions, and its tendency was advantageous to public safety and convenience. A very great stimulus had been given to improved education which such a measure as the Pharmacy Act would infallibly prove. Its effects were even now apparent, for in no previous year had he seen the laboratories at Bloomsbury square filled with more learned and intelligent students. The President remarked, with regard to the sale of poisons, that it was remarkable that no law should have been passed to regulate it in this country, till the Arsenic Act was passed in 1851, but in France so far back as 1353, nearly 500 years before, a law was passed to regulate the profession of apothecary and herbalist, and to subject their shops to inspection. The President quoted some curious extracts from this enactment, and then spoke of the public recognition of the services of Mr. Sandford to the cause of pharmaceutical education, plate to the value of £200 having been given to that gentleman by members of the Pharmaceutical Society in May last, and the balance of the amount subscribed was to be expended in a portrait of Mr. Sandford to be placed on the walls of the institution for which he had laboured with so much devotion and success. The President then passed in review the progress of scientific Pharmacy for the year, especially noticing the labours of Mr. John Eliot Howard, on the chemistry and physiology of Cinchona as shown in his recently published work on the Quinology of the East Indian Plantations. The President gave some interesting facts in connection with this subject, alluding to the so-called *missing process* which seemed to be destined to play an important part in cinchona culture. This process consisted in covering the stem from which a strip of the bark had been removed with moss. The wood thus laid bare exuded a delicate cellular tissue, having the appearance of minute gelatinous drops, which gradually increased and hardened, and ultimately formed a new layer of bark. An interesting fact in connection with this new bark was, that it was richer in alkaloids than that which it replaced, and the bark of the second renewal was richer than the first, and the third than the second. This increase of the alkaloids was considerable—in some cases almost double—and it was also stated that the bark of the third renewal was better fitted for the extraction of quinine than normal bark, and yielded its alkaloid in a state in which its purification was singularly easy.

The President then passed in review the labours of Mr. Broughton, in the same field, for the Madras Government, of Mr. Lefort in the comparative examination of the Ipecacuanha of Brazil and that of New Granada; and also spoke of the method of distilling the various herbaceous plants of this country, and concluded by noticing the various subjects which were to engage the attention of the meeting.

Papers were then read by Mr. E. Smith, of Torquay, on Pharmaceutical Responsibility and Remuneration, which provoked the longest and most animated discussion of the session; by Mr. Carteigh, on Syrup of Iodide of Iron; on Distillates, by Mr. Ince; on the Preparation of Lard in Pharmacy, by Mr. Edward Smith; on the Spectrum Analysis, as applied to Pharmacy, by Mr. Stoddart; on Syrup of Phosphate of Iron, by Mr. T. B. Groves; and on Ipecacuanha, by Dr. Atfield.

Mr. Evans called the attention of those present to an engraving of Mr. Jacob Bell, which hung over the President's chair, and said that it had been engraved with the intention of applying the fund raised by the sale of copies to the foundation of a scholarship, or prizes for encouraging the study of Pharmacy.

The committee on a year book had considered two plans—one was the offer of a publisher to publish the work for £200, and allow the society 1,000 copies of the work for that sum, and the other was to publish the book on their own responsibility, at a cost of £250. It was resolved to accept the latter alternative. A paper was read by Mr. G. F. Schacht, of Clifton, on "The Opportunities for Scientific Education in the Provinces." By the provisions of the New Pharmacy Act, all young men entering the business of chemist and druggist may be educated, to a certain point, in chemistry and botany, and great difficulty was experienced in small places, in obtaining instruction in those sciences. Mr. Schacht calculated the number of young men thus requiring instruction as 1,693 in every year. For these, full opportunities for instruction existed in only 29 towns, and inferior opportunities in only about 88 more, leaving a large number, even of towns, unprovided with the means of scientific education. Mr. Schacht recommended the establishment of Local Pharmaceutical Societies; a system of readings in chemistry, such as he had given at Clifton, and the employment of science and art teachers in those places where Government Science and Art Schools existed.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

WE last week gave a full report of the Presidential address, which, as a summary of what has been done in the whole realm of science during the year, is always looked upon as of the first importance, and naturally takes precedence of the Sections. Amongst these latter Chemistry and Biology are the most intensely interesting to our Profession. This year there was no address in the Biological Section, but in that devoted to Chemical Science, the President, Dr. H. Debus, F.R.S., F.C.S., delivered a most interesting one, of which we proceed to give an abstract:—

ADDRESS OF PRESIDENT OF CHEMICAL SECTION.

Dr. DEBUS said: I believe it has been the custom with many of my predecessors in this office to place before the members of the British Association a report of the progress of Chemistry during the year preceding their election. In attempting to follow their example, I soon found that it would be impossible for me, without making too great a demand upon your time, to give even a bare outline of the more important chemical work done during the year. A science, the report of whose yearly advances fills about 1,000 large octavo pages, cannot by any powers of mine have its progress chronicled in an address of half an hour's duration. The best course open to me, under such circumstances, is to direct your attention to the ideas which at present guide chemists in their researches; to place in a clear light the objects they are striving to attain; and to indicate the direction of the scientific thought of our time. To do this is by no means an easy task; for the more manifold and diversified the objects of a science become, the more numerous and extensive its relations with other branches of knowledge, the more difficult it becomes to draw a picture of its actual condition. It is always an excellent recommenda-

tion of a theory or hypothesis when, among the cultivators of the science to which it pertains, very little difference of opinion exists as regards its admissibility and scientific value. This is in a high degree the case with regard to the atomic theory. The vast majority of chemists, I believe, accept this theory as the most suitable exponent of the fundamental truths of their science; and certainly if the quality of the tree may be judged by its fruit there is no other view which furnishes a clearer image to our minds of the chemical constitution of bodies, and at the same time conduces to the discovery of as many important facts and relations. On Dalton's profound hypothesis all bodies are supposed to be composed of atoms of infinitely small dimensions. But these atoms are supposed not to be single: two or more of them are held together by certain forces, and thus constitute what is called a molecule. One atom of carbon, one atom of calcium, and three atoms of oxygen, joined together by the force called chemical affinity, constitute a molecule of carbonate of lime. Vast numbers of such molecules bound to each other by the force of cohesion form a visible piece of chalk. If a chemist wishes to examine a body, his first endeavour is to ascertain of what sort of atoms the body is formed. This is a mere matter of experiment. He next determines how many of such atoms are contained in each molecule of the body; and finally he ascertains how these atoms are arranged, or, more correctly, combined within the molecule; for it is quite clear that a substance like saltpetre, which contains one atom of nitrogen, one of potassium, and three of oxygen, may have these atoms arranged in very different manners and still have the same composition. We might assume the potassium and nitrogen in more intimate union, nearer to each other than they are to oxygen, or we might consider nitrogen and oxygen more closely packed together, and, so to speak, attached as a whole to the potassium; in both cases, saltpetre would have in each molecule the same number of atoms, and the weight of the molecule would be the same. The three determinations just mentioned are of fundamental importance to the chemist; not that such inquiries are the only ones which interest him, for we shall in the sequel notice others of almost equal importance. Nor must it be supposed that questions of this nature are of quite a modern date; for Leucippus, 500 B.C. appears to have sought to explain the nature of things by the assumption that they are formed by the union of small particles, which latter received the name of atoms from Epicurus. It is true the notion of atoms as conceived by the Grecian philosophers is not quite the same as ours, but their speculations contain our notions pretty much in the same way as the acorn contains the oak tree. The determinations of the quality of the atoms in a molecule, or the analysis of the latter, has not undergone many changes during the last few years, and the same may be said about the finding of the relative weight of a molecule, or the determination of the number of atoms which are contained in it. With regard to the latter point, however, it may be mentioned that Avogadro's hypothesis, according to which equal volumes of gaseous substances, measured at the same temperature and pressure, contain the same number of molecules, guides us chiefly in assigning to each molecule its relative weight and its number of atoms; this hypothesis has won more and more the confidence of chemists, and it is now admitted to hold good in nearly all well-examined cases. Our views relative to the manner in which atoms are arranged in molecules, and our methods of ascertaining this arrangement, have, however, undergone great alterations and received great additions during the last ten or fifteen years. To a consideration of these changes, I will now, for a short time, invite your attention. Since our modern views, however, originated in a great measure in the study of organic bodies, and since the majority of chemists now devote their time and labour thereto, I shall confine my remarks principally to the organic branch of the subject. Eighteen years ago, Professor Williamson read before the members of this Association a remarkable paper which contained the germ of our modern chemical views, and was the cause of many important discoveries. He proposed to regard three large classes of bodies, acids, bases, and salts, from the same point of view, and to compare their chemical properties with those of one single elected substance. For this term of comparison he chose water. New water is composed of three atoms, two of hydrogen and one of oxygen. Williamson showed that all oxygen acids, all oxygen bases, and the salts resulting from a combination of the two, can, like water, be considered to be composed of three parts or radicals, two of the radicals playing the part of the hydrogen atoms in water, and the third

that of the atom of oxygen. Potassic hydrate is water which has one of its atoms of hydrogen replaced by an atom of potassium, hydric nitrate is water which has one atom of hydrogen replaced by nitric oxide, and potassic nitrate is water with one of its hydrogen atoms replaced by nitrate oxide and the other by potassium. This speculation, as every chemist knows, is well supported by experiments; it embraces three large classes of bodies which till then had been considered as distinct. Mr. Gerhardt, in 1853, extended Williamson's views by distinguishing two other types of molecular structure represented respectively by hydrogen and ammonia; and succeeded, by help of the radical theory, in arranging the majority of the then known substances under one or the other of the three types already mentioned. Like every theory which is in harmony with experience, the above considerations led to results of unexpected importance. For it soon became apparent that the radicals which thus replace hydrogen in water are not at all of the same chemical value. The learned gentleman entered into an elaborate and technical explanation in proof of this statement, and then went on to say:—Thus every year produces results which improve our conceptions of the atomic and molecular constitution of bodies. And as our knowledge improves, new questions suggest themselves, and our power over the elements increases. It has already become possible to prepare in the laboratory bodies of a very complex character, and which a few years ago were only found in the bodies of animals or plants. Alizarin, the beautiful compound of the madder root, has been obtained by artificial means in the course of the year by Messrs. Liebermann and Græbe. Results of such a nature render it highly probable that, at no distant period, it will be in our power to prepare artificially nearly all, if not all, the substances found in plants and animals. Here I must not be misunderstood. Organic structures, such as muscular fibre or the leaves of a tree, the science of chemistry is incapable of producing, but molecules like those found in a leaf or in the stem of a tree, will no doubt one day be manufactured from their elements. I must not conclude this address without reference to two or three papers of great importance. Professor Bunsen, of Heidelberg, has published a paper on the washing of precipitate. Every one acquainted with practical chemistry knows how much time is often lost in waiting for a liquid to pass through a filter. Bunsen found the rate of filtration nearly proportional to the difference between the pressures on the upper and lower surfaces of the liquid. If, accordingly, the funnel be fixed air-tight by means of a perforated cork to the neck of a bottle, and the air exhausted in the bottle, the liquid will run faster through the filter in proportion to the diminution of the pressure in the bottle. Comparative experiments, some made according to the old, and others made according to the new method, showed that the filtration, washing, and drying of a precipitate, which took seven hours by the old plan, could be performed by filtration into an exhausted bottle in thirteen minutes. But a saving of time is not the only advantage of the improved method of collecting and washing precipitates. A more perfect washing, with less water than is required by the common way of proceeding, is by no means the least recommendation of Bunsen's ingenious method. A very important paper has been published by Professor Liebig on the improvement of the nourishing qualities of bread. Certain quantities of phosphates and other salts form necessary ingredients of wholesome food. Now, it is well known that most of these salts, which naturally exist in wheat, remain with the husk. Liebig proposes to add salts, of a nature similar to those remaining in the husk, to the flour, and at the same time to substitute for the carbonic acid developed by fermentation gas liberated from sodic carbonate. The bread prepared according to Liebig's recommendation is said to be of excellent quality, and to exceed in value bread made by the ordinary method. Mr. Graham, of Her Majesty's Mint, has continued his researches in the absorption of hydrogen by palladium. Palladium appears to be able to absorb more than 900 times its volume of hydrogen, and to form a combination which consists of nearly equal equivalents of the two elements. Hydrogenium, as Mr. Graham calls the combined hydrogen, acts in this case like a metal, and thus the opinion held by some scientific men, that hydrogen constitutes the vapour of a metal, receives confirmation. The specific gravity of hydrogenium, as contained in the alloy, was found to be 1.95. These experiments are remarkable in more than one respect. The palladium which absorbs and combines with the hydrogen, does not change its state of aggregation, but remains solid and expands as if it had been heated. The nodules of the palladium have consequently changed their relative positions, and com-

bined with hydrogen, whilst the continuity of the metal remained intact. The last paper to which I have to draw your attention is to the beautiful paper by Professor Tyndall, on a new method of decomposing gaseous substances by means of light. Tyndall's experiments bring us face to face with the motions of atoms of molecules, and the relation of these motions to chemical decomposition. They will no doubt, at some future time, furnish valuable materials to chemical dynamics.

Literature.

A HISTORY OF CHEMICAL THEORY.*

THE first of these is the introduction to M. Wurtz's "Dictionary of Chemistry." Mr. H. Watts viewing this as an important monograph, of which we have no exact counterpart in the English language, has presented it to us in our native tongue. It is no great compliment to say that, from many circumstances, there could not be a fitter translator.

As we have already reviewed this introduction in the original language, it is only necessary to notice the editor's share in the work. Mr. Watts, in his Preface, is obliged to offer a sort of an apology for what he terms "the national partiality." We were, perhaps, the first to call attention to this marring of a valuable book by the use of illiberality, and our ideas have been forcibly endorsed by subsequent reviewers. If this bias culminated in such sentences as "chemistry is a French science," &c., it would be very unimportant; but the more we have become acquainted with this book, the more we are convinced that *M. Wurtz's chemistry is simply French chemistry*, and that he has not sufficiently studied universal chemistry.

The text of the original is literally and carefully translated in the present edition without comment or omission. The editor has, however, added his remarks in notes, which he keeps distinct from the original notes by marking with letters instead of numerals. The first of them is a long one, in which he proves that the statement that chemistry, as a science, was founded by Lavoisier, requires some qualification. He also says the first great generalisation of the facts of chemistry was undoubtedly the phlogistic theory of Stahl. Now, this theory took no account of the relation of weight between a combustible body and the products of its combustion, directing attention exclusively to the visible phenomena, the evolution of light and heat, attending the process; and it was, perhaps, by a natural reaction that, when the real nature of the change and the great importance of the increase of weight experienced by the burning body had been brought to light by the discoveries of Lavoisier, the attention of chemists should for a considerable time have been chiefly directed to their ponderal relations, and that even the good and valuable points in the phlogistic theory should have been, for the most part, overlooked. But, on viewing these phenomena by the light of recent investigations, it must be admitted that the thermal changes attending the process of combustion are quite as important as the ponderal changes.

Even those who are the happy possessors of the "Dictionnaire de Chimie" should get this English version of the introduction. It is an invaluable accompaniment.

The first five parts of M. Wurtz's "Dictionary" give us a very good idea of the character, scope, and value of the work. As regards the arrangement, the publishers state in their advertisement that the work is not, properly speaking, a dictionary—that is to say, it is not merely a vocabulary containing words and their definitions, but it is a collection of monographs upon the different objects of the science. The alphabetical arrangement would appear to be the only point of resemblance to the dictionary form. There are eighteen collaborators, who are, however, under the generalship of M. Wurtz ("*une grande unité de rédaction.*")

This little army contains certainly the cream of the French chemists, if we except MM. Dumas, Berthollet, and a few others. It consists of—Bouis, Caventon, Ph. de Clermont, Debray, Deherain, Delafontaine, Friedel, Gautier, Grimaux,

* "A History of Chemical Theory, from the Age of Lavoisier to the Present Time." By A. Wurtz. Translated and Edited by H. Watts. London: Macmillan and Co. 1869.

"Dictionnaire de Chimie, Pure et Appliquée." Par A. Wurtz. "Histoire des Doctrines Chimiques depuis Lavoisier, &c., et 1er à 5e Fascicule." "Abichite" à "Ceruse." Paris: L. Hachette et Cie 1868 and 1869.

Hautefeuille, Kopp, Lanth, Le Blanc, A. Naquet, Salet, Schutzenberger, Roost, and Willan.

They all seem to have borne the heat of the work, and to have done their share. There is no doubt that this important book has been suggested by "Watts' Dictionary of Chemistry" (published within the last few years in England), which it follows closely in the general outline and arrangement. We have no doubt that the desirability of possessing a similar work in France was stimulated by the deserved success of the first-named book. M. Wurtz's "Dictionary" possesses, however, one radical difference, which is a decided advantage. It is a dictionary "*pure et appliqué*," and equally devoted to technical and theoretical chemistry.

We cannot speak too highly of the illustrations, which are excellent and most useful in such articles as require description of furnace or still arrangement. Also, the great superiority that our French neighbours' drawing of crystals exhibit to the unsatisfactory outline sketches given in our works on mineralogy. Here all the crystals are drawn in perspective and are artistically shaded. The value of such a mode of illustration is at once evident.

The following are some of the most important articles in the number received:—"Acids" and "Amines," from the pen of M. Naquet. "Alcohol" and "Steel" are articles well written and well illustrated. "Alcoholimetry" is rather meagre. Under this head is given a list of these compounds:—Aniline, Alkaloids, Assimilation, and Atomicity, &c.—the last an excellent series of articles by M. Wurtz. Also we may specially mention Benzol, Bile, Bleaching, and Carbon.

MENTON AND SAN REMO.*

WE are here presented, from the hands of a well-known author, with a small but sensible volume on Menton and San Remo, two of the foreign winter health resorts which seem to have a really sound and good reputation.

The short description of Menton given in the first few pages of Dr. Edwin Lee's book is concise and to the point; and it is with regret that we find so good a writer and describer breaking off for the sake of slipping in a highly-coloured description of "secluded valleys" and "mountain torrents." Perhaps, however, our writer may elect thus to change from the plain to the poetical, and, at any rate, we must allow that all his very numerous quotations from authors seem to us well and wisely chosen.

In the description of San Remo we are pleased to find Dr. Lee familiar with the well-written and highly-interesting pamphlet of Dr. Prosser James, published some years ago, when San Remo was but little known.

For our own part, while experience obliges us to speak favourably of Menton as an eminently good winter residence for many phthisical invalids, we have a preference for San Remo as being less confined and more bracing than Menton, while at the same time it is warm and free from cold draughts.

The second half of Dr. Lee's work consists of very good advice in the selection of a winter climate. The importance of exercise in a dry bracing air is thoroughly insisted on; people are to be taught that *the risk they run in staying indoors, not in going out*. Another recent writer on the climatic treatment of consumption† has strongly urged this point of exercise out of doors as being the nearest approach we have as yet found to be a specific for the cure of consumption. Our own experience is entirely in accordance with this; indeed, we should say the surest way to make consumption inevitably fatal would be to shut the invalid up in one room and give him plenty of cough mixtures of opium, squills, tartarised antimony, and so forth. This is the way consumption was treated formerly, and is too often treated now, and no wonder at its being called the *scourge of our race*. We are, however, wandering away from Dr. Lee and his book. A few pages at the end of the work are devoted to a short notice of Porto Maurizio, a small seaport near San Remo, to which Dr. Lee had his attention drawn by Dr. Panizzi last winter. Porto Maurizio seems worthy some attention as a seaport, and possesses already a certain amount of accommodation for visitors.

Dr. Lee's book is by no means an expensive one: it is simply got up, as if intended for use; and, seeing the amount of information it contains, both respecting Menton and San Remo, as well as on climatic influences generally, we recommend those to read it who are intending a sojourn in the district of the Riviera during the coming winter.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ON THE BOILING OF LIQUIDS.—MEANS FOR PREVENTING BUMPING.

HUGO MÜLLER says that Pietro Pellegio's processes for the above purpose are quite ineffective. M. Pellegio's method consists of a moderately-wide glass tube passing nearly to the bottom of the retort, the upper end being bent at right angles, and draw, out into a capillary tube. E. Winkelhofer has proposed for the same purpose the application of an electric current. M. Müller says that the most satisfactory mode is to introduce through the cork in the tabular of the retort a glass tube, which is drawn out to a capillary tube, and pressed tightly to the bottom of the retort. The upper end of the glass tube is connected by an indian-rubber tube with a generator of carbonic acid, hydrogen, or gas-holder containing air. Under these conditions all bumping is avoided, and the distillation proceeds with the utmost facility. For ordinary purposes, the author introduces into the liquid about to be distilled a small fragment of sodium amalgam, or in cases where the liquid is acid, a small piece of sodium tin.

Methylic alcohol is well known to be one of the most difficult liquids to distil; yet, on the introduction of a minute piece of sodium amalgam or sodium tin, it can be distilled with perfect steadiness, and without exhausting the sodium tin.

The action of these substances is due to the minute but continuous disengagement of hydrogen gas taking place during the process of distillation.

PRESERVATION OF PROTOSULPHATE OF IRON.

M. Wellborn states that protosulphate of iron is absolutely preserved, and kept without even the least trace of oxidation, by placing with it a piece of camphor wrapped in a piece of clean and dry paper.

ETHYL-HYPOSULPHUROUS ACID.

Mr. R. Smith has endeavoured to prepare a class of salts in which an alcohol radicle is introduced into the formula of the hyposulphites. The author starts by preparing ethylic sulphide by the action of ethylic chloride on protosulphide of potassium and ordinary alcohol; in about half an hour heat was applied to the retort, when a distillate having the odour of garlic and rotten cabbage came over it, consisting of ethylic sulphide, alcohol, ethylic chloride. Water was added which separated the oily sulphide. This was, after rectification over chloride of calcium, found to have a boiling point of 81° C., not 73° C., as given in the manuals. About six ounces of this sulphide was treated with an equal bulk of strong sulphuric acid, and the oil acquired a bright red colour and a decided fluorescence. A large quantity of water was added, and the whole neutralised with pure barium carbonate, and filtered from the insoluble sulphate of barium. In a few days beautiful colourless transparent crystals were separated, and which were very regular rectangular plates. On analysis, these crystals were found to have the formula—

or barium ethyl-hyposulphite. The author also prepared the copper, silver, and sodium salts. He is now experimenting on methyl- and amyl-hyposulphites.

The same journal (*Journal of the Chemical Society for August*) contains a long and elaborate research "On the Constitution and Reactions of Tyrosine," by Dr. Thudichum and Mr. Wanklin. It is too long to do justice to by any summary, but it treats of the oxidation of tyrosine by chlorine acid, the action of mercuric and mercurous nitrites and nitrates on tyrosine, the action of nitric and nitrous acid, and also on the action of iodide of ethyls, and of reducing agents.

SOLUBILITY OF PEROXIDE OF IRON IN SUGAR.

In the July number of the *Pharmaceutical Journal* appeared a paper from the pen of Mr. Water G. Smith, entitled, "Note on the so-called Soluble Peroxide of Iron." This compound occurs in small cubical, reddish-brown crystals. When a few grains were treated with water, the sugar, of course, is readily soluble, but the author said it was manifest at once that the peroxide of iron is simply adherent to the surface of the crystals of sugar. The filtered solution was tested with ferrocyanide of potassium, sulphocyanide of potassium, and sulphide of ammonium. No precipitation or colouration ensued, except the slightest possible tinge of blue with the ferrocyanide of potassium. "So far, then," says the author, "from its being perfectly soluble, or only a trace of the iron remaining insoluble, not a particle of the oxide is in solution." The amount of Fe₂O₃ present in the article was '47 per cent. The August number of the *Pharmaceutical Journal* contains in reply a note from Mr. Woods, in which he says:—"It would appear that iron sugar does not retain its solubility for an indefinite time, and I infer that the sample which Dr. Smith examined had passed into the insoluble stage before he received it." The same number contains processes by Siebert for making this preparation, and also another by Drs. Kœhler and Hornemann. We give the latter: Equal weights of ferrum sesquichloratum solution (15 per cent.) and simple syrup are mixed, hydrated soda is then added until the precipitate is entirely redissolved, and the filtrate is mixed with a large quantity of distilled water, and boiled for some time. The presence of the neutral salt, Na Cl, is sufficient to precipitate the hydrated oxide of iron in its soluble modification, the precipitate is collected on a filter, washed until the filtrate ceases to precipitate silver salts dissolved with powdered sugar, and the solution evaporated to dryness.

SALTS OF THE MAGNETIC OXIDE OF IRON.

M. Lefort forms these salts by precipitating a ferrous ferric salt by caustic potash, and then dissolving this oxide in the acid it is intended to form the salt of. This solution is left to crystallize while standing over sulphuric acid. The author has found the chloride as a crystalline mass, having the formula Fe Cl + Fe₂ Cl + 18 HO. The author had also formed the sulphate. The solutions must be evaporated at a low temperature, as all the salts of the magnetic oxide are decomposed by a heat far below the boiling point of water.

NEW SULPHUR ACID.

M. Schutzenberger describes a new acid. This is said to be made up of a double atom of sulphurous acid wherein one atom of oxygen is replaced by one atom of hydrogen. It is an anhydrous acid represented by S₂O₃H. Some of its salts have been prepared in a crystalline form.

CIENTA VIRORA.

M. Van Ankum says that the active principle of this plant is an essential oil belonging to the camphine series, and is composed according to the formula C₁₀ H₁₈. The root does not contain any alkaloid at all (? Ed. S.).

ERUPTION OF THE SKIN CAUSED BY AN INSECT FOUND IN DAMAGED WHEAT.

In some parts of France, from the heavy rains of last year, the wheat was damaged. The persons employed to turn it over became affected with a very troublesome eruption, which, commencing with painful itching, ended in the course of a few hours in redness and a miliary eruption, which disappeared in the course of three or four days. M. Rouyer noticed a great many small black moving points, of the same nature as those observed on the damaged wheat. Examined under the microscope, he found them to be acari.

ELECTRICITY FOR LESSENING PAIN IN EXTRACTING TEETH.

Although dentists have long since discarded the use of electricity for lessening pain in extracting teeth, Dr. Pallas, of Bordeaux, has been attempting to bring it again into notice, believing that its failure has been caused by the irregular distribution of the electricity. He has invented an instrument which he considers will obviate this difficulty.

INDIAN MEDICAL SERVICE.

The Military Secretary, India Office, presents his compliments to the Editor of the *MEDICAL PRESS*, and begs to enclose, for publication, a list of the Candidates for Her Majesty's Indian Medical Service, who were successful at the competitive examination at Chelsea, on the 9th of August last.

Forty candidates competed for forty appointments. Thirty-nine were reported qualified.

COPAIBA AND CUBEBS IN CROUP.

Mons. Trideau, some time back, published twenty-six cases of croup which he had treated successfully by these drugs. At the meeting of the Société de Therapeutique of Paris, Messrs. Burgnon and Labrie found that by giving the oleo-resinous extract of cubebs in syrup, they had overcome the repugnance of children to this drug. In one case reported of its efficacy, the false membranes softened and disappeared in a very short time.

HYDATID CYST IN THE BRAIN.

The patient, a female, had suffered first from intense headache. At the end of ten months her mind became feeble; later, vomiting set in of a distressing character, then difficulty in swallowing, retention of urine, and paralysis of the sphincter ani; and for five months before death, complete paralysis of the left side, dyspnoea, and feebleness of sight—first of the right eye, then of the left. After death a large hydatid cyst was found, occupying the whole of the anterior lobe of the brain.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, SEPTEMBER 1, 1869.

VACCINO-PHOBIA.

If our forefathers could rise from the dead—a supposition often spoken of in relation to the advances that have been made—one of the most astonishing sights they would witness, and the one that might in real interest eclipse the wonders of steam and electricity, would be the prevalent beauty of the population. Instead of a mass of faces pitted with small-pox, they might walk the length of street after street without encountering one visage marked by the great destroyer of the beauty of

“The human face divine.”

Seeing this they would naturally conclude that small-pox was no longer so fatal a disease as in their time; and our mortality records would prove that the supposition was correct. That this diminished mortality and banishment of disfigurement is the result of the general practice of vaccination scarcely any educated men will be disposed to question. Yet, in the presence of these great facts, there are some superstitious and prejudiced people who resist the innovation, and would set themselves up as martyrs. For them there is little hope, and need be little pity; but, unhappily, their folly endangers those over whom they have control, and through them the community at large. Moreover, they know no limit to their desire to proselytize, and they prey upon the prejudices of the most ignorant and most susceptible. It is sad that they cannot find vent for their efforts to denounce the evils of the age in spheres in which they could do only good. With drunkenness and hundreds of other vices holding revel around them, they shut their eyes to all, and devote their denunciations to the disinterested efforts of the Profession to hold in check disease and death. It is a sad perversion of their powers, and one which would almost make us pity their want of discrimination.

These enthusiasts have lately held high holiday. They have induced, here and there, a mother to resist a law

made for the good of her offspring, and sung their pæans over ignorant maternal love, suffering condemnation by the magistrate rather than risk injuring innocent childhood. Surely, however, it would be more in harmony with their professions to endeavour to inform the maternal mind, instead of exciting its natural fears and stimulating its ignorant prejudices.

There is not the least doubt that the busybodies who encourage resistance to a beneficent law have much to answer for. Could they but see the danger of their teachings they would hesitate before they undertook the rôle they seem so anxious to play. Place before any mother a just estimate of the chances, and we venture to say that she would gladly see her babe fret for a week, while its arm was sore, to protect it from the awful risks that exposure to the contagion of small-pox entails. But this is not the course adopted by the fanatics. The maternal fears are preyed upon by spectres that have no real existence, the maternal instinct is alarmed by tales as unreal as the goblin stories that terrify children; and because the consequences of neglect are not immediate, the superstition lives and thrives. We do not say it spreads, for there have always been firm believers in *post hoc ergo propter hoc*; and from the time of Jenner some of these have been ready to attribute all manner of evil to the little vesicle that has preserved so many from one of the direst diseases.

There is, however, hope even in the dark abyss of ignorance that reigns about us. Some of the high priests of the *post hoc* faith can prophesy quite as effectively against other things. When one says this is all because of vaccination, another is equally confident that it results from astrological influences; another, that it arises from the introduction of tea into England; another, from tobacco; another, from corn flour. Others assure us that it is the influence left in the air since cholera came; others are as certain that the potato disease brought it; and we shall not feel surprised if some patient next week lays all the blame on the innocent lady-birds. A patient of our own has traced all the evils that the vaccino-phobiacs attribute to the cow-pox to the disturbance of electrical conditions caused by laying so many miles of good conductors; in the form of railroads, all over the country. Another patient, despising the *propter hoc* as unworthy of his faith, finds the explanation of everything in the Book of Revelations; but we are hardly well enough versed in his views of prophecy to anticipate the work he will, perhaps, issue on this important subject, and which will, at least, serve one good end by demolishing the anti-vaccination fanatics.

The few cases of resistance to the compulsory vaccination law that have come before the magistrates are scarcely worth the attention that has been bestowed upon them. In the present day a press always present tells the tale far and wide, and to this we attribute the notion of some of our contemporaries that the objections made are at all new. From the first dawn of the discovery these objections have all been urged, and have been answered a thousand times. The great Jenner encountered obstacles of which those unfamiliar with his struggles little dream. He was assailed at once by ridicule and every weapon that prejudice and ignorance usually employ; but he met them all calmly with the strength of facts, the love of truth, and the appeal to experience which has convinced all but a few who set themselves up as superior to such arguments, that vaccination is a full and efficient protective against small-pox. Those who pretend that a population of pitted faces would

be preferable to what we now live among—that blindness so often caused is a risk worth running, that the diminished number of deaths is not a triumph—must be left to dwell upon their own ideas until they are tired of them, but cannot be trusted with legislation for the public health.

There is, however, another class of persons for whom we have the highest respect, and to whom a word may be due. When scholars like Prof. F. W. Newman enter the arena, we may listen with respect. But what does his letter allege or imply? Nothing, but some alarm at the rash statements lately made by the fanatics, and too great a readiness to trust a single authority. He quotes the late article in the *Westminster Review* on "Prostitution" as giving support to the notion that a hateful disease almost universally pervades the English people. Now, this is not so. The writer in the *Review* is clearly one of our own Profession, and, if we rightly judge, one who would speak out his conclusions, however distasteful they might be. He evidently, too, set himself the task of showing the importance of the subject he treated by proving how widespread was the disease in question. But he would surely regret that Mr. Newman should understand him as he appears to have done. We are inclined to look upon this as the weak point in the *Westminster's* powerful article, and one which the writer might set right in a note to his concluding portion, which is to appear in the next number of the *Review*. If anyone would assert that syphilis has increased in consequence of vaccination, we should simply deny the assertion and ask for proofs. The only facts that could be brought forward to show that such a result had followed the operation occurred on the Continent, and have not been at all accurately recorded, still less understood; and they were but isolated accidents, due, if they occurred, to such a degree of carelessness as English medical men have never been guilty of. When whole generations have been safely vaccinated, and thereby effectually secured from one of the most awful and loathsome of plagues, it is folly to ransack the Continent in search of two or three instances in which some bad consequences may have occurred from carelessness in performing the operation.

SCIENTIFIC AND MEDICAL CONGRESSES.

THE annals of every scientific association abundantly prove that no class is more interested in scientific progress than our own Profession. No other section of society contributes so largely to the advance of this kind of knowledge. It is but natural, therefore, for a strictly professional journal to devote considerable space to the Annual Scientific Congress. In our last issue we gave in full the masterly Address of the President, feeling that to divide such a well-knit discourse was, in fact, to spoil it, and that there were other subjects discussed that could more properly be postponed.

Congresses, although modern movements, have now attained an age that renders them to the rising generation established institutions. The Association before us took its rise in the troublous time that preceded the first Reform Bill—a clear proof that men of science were not to be turned from their chosen pursuit by the wider agitation that prevailed. The first meeting was held at York in 1831, since which time the annual gatherings have been regularly growing in size and importance.

Prior to that epoch there was no such association in these islands, although Germany had held such congresses for a whole decade, and, indeed, the German Congress may be looked upon as the parent of our own. Not that

there was any lack of learned societies taking cognisance of science. The Royal Society dates from 1622, and received from Sir Isaac Newton the priceless present of the MS. of his *Principia* in 1686. The Society of Arts dates from 1753. The Manchester Literary and Philosophical Society from 1781, and the Edinburgh Royal Society from 1782. This brings us to a time when societies were more rapidly formed, as a want for them was felt. The Linnæan Society began in 1788; Royal Institution, 1800; London Institution, 1805; Geological Society, 1807; Royal Astronomical, 1820; Royal Geographical, 1830.

All these societies differ, however, vastly in their organization and mode of action from the British Association, and though each may accomplish in its sphere more than can be expected from the one peripatetic body, none can expect to rouse the public interest so fully, nor to measure general scientific progress so exactly. To compare with any other body, we can only refer to the German Congress, which was originated by Dr. Oken, a Professor in the University of Jena, and held its first meeting,—the first scientific congress the world had seen,—in 1822, at Leipsic. The object of this gathering was stated to be "to give an opportunity to the cultivators of natural science and medicine to become personally acquainted with each other." Observe how necessary it was to obtain the aid of our Profession,—an aid given then, and ever since, with the utmost freedom and even enthusiasm.

Every one who had written a paper on any branch was admitted a member. How very characteristic of Germany, and of the only mode of intercommunication with the scientific world at that date! After the first congress, which was quite successful, annual gatherings were held successively at Hallé, Wurzburg, Frankfort, Dresden, and Munich. This last congress secured the favourable notice of the King of Bavaria, and thus rose in the estimation of the public. The next year, 1828, Berlin was the place of assembly; the King of Prussia and heir-apparent attended the soirée of the President, Baron Humboldt, and thus did honour at once to the great philosopher, and the assembled devotees of science. Two years afterwards, the attendance of some of our countrymen at the German Congress led to the expression of a desire for such a gathering in this country, and Sir D. Brewster's often printed letter to Professor Phillips, which may be called the preliminary act of the first British Congress, held, as we have stated, at York, in 1831. At that meeting, some 350 learned men were present, of whom about ninety, with true British instinct, enrolled themselves as members at an annual subscription, so necessary for such a purpose. The first report was issued the next year, and, with the list of names, only extended to about 100 pages, a very small affair, indeed, compared with the huge volumes that now appear every year.

The originators of the Association could have little anticipated its brilliant career. They confined their first outlay to the cost of the gatherings, but they soon perceived that more might be accomplished than setting up a temporary altar to science in the towns they visited, and kindling a spark of enthusiasm for knowledge among the persons with whom they were brought into contact at their successive meetings. And they were right in attempting more, for they have been able to grant some £33,000 towards the carrying on of important scientific investigations. The medical profession has its own society in imitation of this, but the managers of it should blush to know that, out of a proportionate income, the shillings of the guineas subscribed have not been devoted to the investigation of medical subjects. Would that the example of the original might shame the rulers of the imitation Association into a more sensible application of its funds! Even in medicine proper, the great Association has done more than the little one, which has no other demand upon it. Look at Meteorology, the Kew Observatory owes its existence and continuance to the GREAT BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, and last year more was granted by it to physiological experiments,

on the methyl series, on digestion, &c., than by the *little British Medical Association*, which has nothing else to do, and allows its money to be squandered by a noisy clique. The thirty-seven volumes of Transactions of the GREAT ASSOCIATION contain the material for a history of scientific progress during the thirty-seven years. The half-yearly volumes of the *little Association* contain the small talk, the gossip, and the jealous petty squabbles of the ruling clique of a section of the Profession, and a number of spiteful paragraphs about the conductors of rival journals. Is not the contrast a sad one?

Our readers may be glad to have the list of the annual Scientific Congresses, with the amounts voted for the advancement of science. It is a goodly one and worthy of the notice of the *little medical society* which in less important things loves to imitate it. Here it is.

ANNUAL MEETINGS OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Year.	Place.	President.	Grants to Science.		
			£	s.	d.

Notes on Current Topics.

The Fall of the "Albert."

LIFE insurance has received a great shock. The catastrophe of the "Albert," which absorbed many other offices, and amongst them the "Medical and Invalid," in which, we fear, numbers of our brethren were insured, brings despair to thousands of the most prudent heads of families. It is one of the most disgraceful exposures that could be conceived. We cannot say, as some feel inclined to do about these policy-holders, "Serve them right." Such an expression is far more applicable to the shareholders, who, possessed of some power, let the directors

scatter their property uncontrolled. They have lost all they invested, but when they have paid up to the uttermost their liabilities will not be met. Yet a scheme is put forward to reconstruct this Office in a way to give the shareholders a share of future profits. Nothing could be more monstrous. What is it but paying them for having brought about all the mischief? Rather a thousand times let Chancery swallow up what it may. It is no case for lushing up and trying to hang together. We would advise the policy-holders to beware of any specious offer, and all who can overcome the first loss will find it the least. Much discussion is taking place respecting Government control, but that question can hardly be settled by a single example—gigantic as this is. Surely proprietary offices, after this, will be forsaken for mutual ones.

Indian Medical Service.

It has been ruled that a medical officer in charge of a regiment, appointed to officiate in a staff appointment during the absence on furlough of the permanent incumbent, will not be required to vacate his regimental charge.

Health of the Emperor of the French.

SEVERAL of our correspondents in Paris allude to the rumours respecting the health of the Emperor, but they differ widely in their opinions.

The Emperor has stone, says one, and will not let Nélaton crush it, as he was unsuccessful in the case of Niel, and His Majesty is very superstitious. Another says the Emperor suffers from gravel, causing him much pain in the loins, and once or twice hæmaturia. The Emperor is not very ill, declares a third; he has lumbago and other rheumatic pains, and has for years been subject to piles.

Our readers will readily understand these varying rumours as arising from such symptoms as could not be concealed, but are common to each proffered explanation. We may allude to a more probable conjecture by one who avers that none of the papers know anything about it, but believes that the official contradictions as to the Emperor's danger may be reconciled with what is known of the treatment pursued, by the supposition that an enlarged prostate is the cause of the trouble. This would not be unlikely, considering the advancing age of the Emperor, and would not imply danger. On the other hand, the Emperor suffered from gravel several years ago. Those in attendance give no information whatever, so that it is impossible for newspaper correspondents to give more than rumour and conjecture.

The Great Water Question.

WE gave last week the evidence of a leading engineer. Our readers are well aware that the chemical and medical evidence is divided, and that a rather bitter controversy has been waged. We have enquired whether the delay in issuing the Report of the Commission did not arise from the pressure brought to bear by those whose views were condemned in order to get that Report modified? No answer has been given, because, we believe, no denial could be put in even by those who had on a former occasion flatly contradicted published statements. A number of the news-

papers have been deluded, by the official position of interested parties, to take up the question of water supply. Articles have appeared, which a literary novice would have no difficulty in fastening on the originators of the hypothesis that has been condemned. Such tactics need no notice. Idle and noisy men may stir up a temporary excitement, but anonymous contributions to non-scientific papers will not settle questions of science. Even so powerful a paper as the *Pall Mall Gazette* cannot expect to grapple successfully with scientific problems, and we are glad to find, in the article that appeared in that journal, a somewhat less confident tone than that which some other editors of dailies have permitted to appear. That paper freely admits that "testimony must be weighed as well as counted," an opinion we have always looked upon as an axiom. Now, take the names first mentioned by the *Pall Mall*,—Dr. Letheby, Dr. Odling, and Professor Allen Miller. As chemical authorities we venture to say they may be weighed against any other three names of living men. But there is something else to be said, each of the three is a Graduate in Medicine. The *Pall Mall* takes on the other side three names,—Brodie, of Oxford, Dr. Frankland, and Dr. Parkes, the last only of whom is a medical man. Dr. Angus Smith agrees with Drs. Letheby, Odling, and Miller, and may be weighed, if it be held that number is anything, against one of the non-medical chemists.

Then, Mr. Simon, though a surgeon, is no chemist, and, unfortunately, is so crotchety and so much dependant on the work of those under him, that we cannot regard his opinions with the deference that his position secures for them in some quarters. He is an adept at framing hypotheses; but this tendency is one that should be curbed in such investigations, and we think that mere suppositions and unsupported speculations ought scarcely to "weigh" much against the facts of science.

Rural Sanitary Measures in India.

THE Chief Commissioner of Oudh recently brought to notice the want of legal authority to enforce sanitary measures in villages and smaller towns, and proposed recourse to legislation in order to give the necessary power to local officers, summary powers being in some cases given in outlying tracts to the police. He was told in reply that Government quite recognized the importance of extending all over the country, as early as possible, some machinery for carrying out at least the simplest and most obvious sanitary measures, but that such reforms must be introduced with the cordial co-operation of the people themselves, and that this would probably be obtained only by degrees. Stringent measures cannot be enforced until the people have been to some degree reclaimed from their old habits by the persevering efforts of the divisional and district officers, by which many of the prejudices and the apathetic indifference of the inhabitants may be overcome. Government relies upon local officers using their best exertions towards this end, and at some future time it may be necessary to give to heads of villages or other local authorities some legal powers to enforce ordinary sanitary measures. Even then, however, the Government is of opinion that punitive measures should be but sparingly used. They will lose a great part of their effect until the people have been fully taught to recognize their use and justice. And, except to enforce the order of a magistrate on the spot, summary powers cannot be entrusted to the police in

such matters. To give such a power of interference, or even the power of summoning an offender before a distant tribunal, would infallibly open a door to great abuse, and would possibly set the popular feeling altogether against useful reforms, which it is impossible effectively even to initiate without the general co-operation of the people themselves.

The New York Drug Bill.

THE following Bill was passed by the last Legislature of New York:—

"SEC. 1. No person employed or in attendance at any drug store or apothecary shop shall prepare a medical prescription unless he has served two years' apprenticeship in a drug store, or is a graduate of a medical college or a college of pharmacy, except under the direct supervision of some person possessing some one of the before-mentioned qualifications; nor shall anyone having permanent charge as a proprietor or otherwise, in any store in which drugs are sold by retail, or at which medical prescriptions are put up for sale or use, permit the putting up or preparation thereof therein, by any person, unless such person has served two years as apprentice in a retail drug store or is a graduate of a medical college or a college of pharmacy.

"SEC. 2. Any person violating the provisions of this Act shall be deemed guilty of a misdemeanour, and shall be punished by a fine not exceeding 100 dols., or by imprisonment not to exceed six months in the county jail; and in case of death ensuing from such violations, the person offending shall be deemed guilty of a felony, and be punished by a fine not less than 1,000 dols., nor more than 5,000 dols., or by imprisonment in the State Prison for a term of not less than two years, nor more than four years, or by both fine and imprisonment in the discretion of the Court."

Deaths by Violence.

SOME statistics respecting the number of deaths from violence in Italy have just been issued by the Italian Government. In 1867, 2,626 homicides were committed, or 10·84 per every 100,000 inhabitants. In Spain, the proportion was 8·24 for the same number of inhabitants; Sweden, 2·02; Great Britain, 1·95; and Belgium, 0·16. The greatest number of homicides occurred in Southern Italy, there being 19·84 for every 100,000 inhabitants; while in Northern Italy the average was 3·70 for every 100,000 inhabitants. Compared with 1866, there was a decrease in 1867 in the total number of violent deaths to the extent of 481. Of the 2,626 homicides committed during 1867, 264 are described as involuntary, 2,259 as voluntary, and 103 as infanticides. Of the last-named there was a diminution of 34 in 1867 compared with 1866.

Jonathan Hutchinson, Esq., Ed. B. M. J.

THE queer mode of procedure adopted by the magnates of the British Medical Association to fill the post of Editor of their Journal, has, for once, ended in a promising manner. The Committee of Council have elected Mr. Jonathan Hutchinson. We congratulate them on having secured this eminent surgeon's services, though, with his rapidly increasing practice and his important public appointments, we should scarcely have supposed even his indomitable energy would have been ready to cope with the

additional work such a post must entail. Without knowing who may have been the other candidates, we may say that none of them will be likely to feel aggrieved at seeing Mr. Hutchinson preferred to them. Under his guidance the Association may hope to see the tone of their Journal greatly raised, and its respectability vastly increased. He is not likely to fill its columns with ungenerous assaults upon individuals, nor with desperate attacks upon classes in the Profession. He will not set class against class, nor college against college, nor, we hope, submit his own unbiassed judgment to the control of a clique. The Journal may thus become a more ready means for intercommunication between members. These will, perhaps, no longer be obliged to send their papers elsewhere for publication, while money is lavished upon getting up sensation reports. One of our contemporaries will lose a valued contributor in Mr. Hutchinson, but all will freely welcome him among the editorial fraternity. We tender him the right hand of fellowship with hearty goodwill, and hope he may be able to devote a full share of his attention to the new work he undertakes.

Professor Halford's Treatment of Snake-Bites.

THE Inspector General Indian Medical Department has, under the authority given in Government Resolution dated the 7th June, had 300 copies of Dr. Halford's memorandum on treatment of snake-bites printed; and a proposal to distribute them among the medical officers of the British and Indian Medical Services, and to the private medical practitioners of the presidency, has been approved by the Government.

We append the paper so printed:—

"The accompanying papers on the treatment of 'snake-bites' are circulated at the instance of Government.

"Should any medical officer, or private medical practitioner, in the presidency of Bombay, feel inclined to treat snake-bites after the manner laid down by Professor Halford, the Inspector General Indian Medical Department will feel much obliged by the cases being made known to him, with notes of each as suggested under the five heads mentioned in the memorandum. Such cases as the Inspector General may receive will be submitted to Government for the information of Dr. Halford, through the authorities at Melbourne.

"By order of the Inspector General Indian Medical Department,

"T. B. JOHNSTONE, M.D.,
"Surgeon Major, Secretary.

"Bombay: 6th July, 1869.

"It is desirable, in the interests of humanity and science, that information concerning Professor Halford's mode of treating snake-bites should be diffused as extensively as possible, and it is necessary that medical gentlemen, who may be inclined to apply the remedy in India, should take careful notes in each case—

"(1) Of the kind of snake by which the bite was inflicted.

"(2) The circumstances under which the patient was bitten.

"(3) The lapse of time between bite and application of remedy.

"(4) If any other, what remedies were applied.

"(5) Result."

THE Sanitary Commission have adjourned their inquiry to next year.

Alarming Symptoms in consequence of Wasp Stings.

A CORRESPONDENT in Huntingdonshire forwards us the following particulars of a case which happened to his brother, the vicar of a parish in the county, which will be read with interest by our readers:—

"Having struck my spade, I suppose, into the very heart of a nest, the wasps came out in great numbers, and in a furious rage, which I suppose intensified their virus. I was at once stung on the left wrist and left eyebrow, and immediately experienced such sensations as I never felt before. As quickly as possible I applied oil, but with little effect. A violent heat came over me and I felt sick; then I turned giddy and spun round and round like a top, till I fell headlong into a currant bush. However, I managed to get up and staggered like a drunken man to the house, and got into a chair, but in a moment fell out of it on my knees, all but fainting. They dashed water in my face, and at length I was able to lie down on my bed; presently I vomited freely, my hands, feet, and chest becoming as red as if I had scarlet fever. I itched all over to a dreadful degree; then I quaked and trembled, and my teeth chattered as if I had a paroxysm of ague—no sleep all night. I felt once or twice as if I were actually dying. Next day convalescent, though feeble. I have been stung by wasps before, but never felt any symptoms like these. Whence the peculiar effect in my system this time? Was I predisposed for the more violent action of the poison? Had these wasps been feeding on carrion, as, I believe, they sometimes do? Or, rather, was I poisoned? What can the toxicologists tell me about it? I should like to know. At all events, I shall be careful how I put my head into a hornet's nest for the future."

The Female Physicians at the Philadelphia Hospital.

AN occurrence of some historical import took place last month. Early in the month the Professors in the Woman's Medical College in Philadelphia told their pupils that as the lectures at Blockley were free to all students of medicine in the city, they had a right to participate if they chose to go. Fifteen, headed by Miss Preston, went in and took their seats. The male students commenced a general clapping of hands and stamping of feet, and were really somewhat uproarious, but the ladies quailed not. All were as silent, unmoved, and dignified as possible. After a few moments, Professor Stillé, of the University, entered, and after the usual applause had subsided, turned to the ladies, and, in a neat speech, bade them welcome, and then commenced his lecture by "*Ladies and Gentlemen.*" After him came Dr. R. Levis, who did not notice them at all, but proceeded with his lecture as if nothing unusual had been presented.

On the following Saturday, thirty-five ladies walked in, and all passed off as before. The next clinic day thirty-three were present. After the lectures were concluded, Dr. Levis invited the ladies through the wards. After the second visit to the clinics, the ladies had Dr. Stillé elected consulting physician to the Female Hospital, and Dr. Levis consulting surgeon to the same, and both accepted.

Chinese Consumption of Opium.

MR. D. B. ROBERTSON, C.B., our Consul at Canton, has sent a somewhat alarming report to the Government of

India on the growth and consumption of native opium in China. The indigenous drug has been steadily improving in quality and quantity, till now it is equal to Malwa, though weaker in flavour. In Canton the opium-smoking shops mix 3-10ths of the native drug with 7-10ths of the Indian. In the interior the native is chiefly used from its cheapness. Mr. Robertson states that the price of the Indian drug must be reduced to hold its own; and even then, if Indian seed were imported into China, the native drug would equal the best Indian. This is probable, for the Chinese would soon learn to manufacture it as well as Bengal civilians and doctors. Meanwhile the value of the import into China has ranged from six millions sterling in 1863 to eleven and a quarter in 1866 and nine in 1868. Everything points to the necessity of abolishing the Bengal monopoly in favour of the Bombay excise system, on commercial and financial even more than on moral grounds.

Poisonous Odours.

L'Union Médicale is very positive on the subject of the deleterious action exercised by the perfume of flowers, especially such as the lilac, jessamine, hyacinth, tuberose, on persons who have the imprudence to leave them at night in the bed-chamber. The more or less fictitious cases of suicide and assassination, which have been related under this head, should not induce us to doubt the reality of the asphyxiating power possessed by strongly smelling flowers. Certain odoriferous fruits share the same deleterious property.

We read in the *Union Bourguignon*, of Dyon, that a grocer who had slept in a small room, in which the contents of three chests of oranges had been piled up, was found asphyxiated in the morning, and was only resuscitated by the most energetic treatment.

Our readers will also recollect a case not long since reported, of death resulting from the odour of quinces, which occurred from sleeping in a room where a large quantity of them were kept.

A CONGRESS of Dentists has just been held at Frankfurt.

THE Illinois Legislature has passed a law classifying drunkards with idiots and insane people, and giving their property and persons to the charge of guardians.

THE late Dean of Durham bequeathed £5,000 to the Northern Counties' Idiot Asylum. Mr. Titus Salt, of Saltaire, has just forwarded a donation of the same amount to the same charity.

At the conclusion of the inquiry into the St. Pancras affair, the Commissioner, Mr. Bere, Q.C., gave no opinion on the case. His report will be presented immediately.

DR. LUSH, M.P., has contradicted a report that he had accepted a Lunacy Commissionership. The honourable member has no intention of resigning his seat in the House of Commons.

DR. FRANCIS HAWKINS and Dr. A. P. Stewart have been elected Consulting Physicians to the Middlesex Hospital. Mr. A. Shaw has been elected Consulting Surgeon. All these have earned the honour by many years of active service.

THREE deaths from sunstroke are reported from the midland counties from the excessive heat of Friday last. In one case the poor fellow became raving mad, but died within two hours of the attack. Death was instantaneous with the other two, all three of whom were field labourers.

THE increase of fever in Glasgow, during so fine a season and so early in the year, is a very discouraging symptom. The accounts from official sources, supplied to the Police Board at their meeting last week, relating to this painful circumstance, are, in fact, rather alarming. The Sanitary Committee were informed by Dr. McGill that there had been 199 cases of typhus fever since their last meeting, as against 159 during the previous fortnight. An increase of close on 25 per cent. in the number of cases within so short a time appears to show an aggressive vigour in this destructive epidemic; and when we consider that it is likely to be reinforced by the fall of the year, now at hand, timely provision should, as far as possible, be made to check its progress. In endeavouring to solve the problem of what is the cause of typhus, specimens of water taken from ten different cisterns have been handed over for examination by Dr. Anderson, whose report on the same is expected against next meeting of the Board.

THE Medico-Chirurgical Academy at St. Petersburg conferred, at its recent annual conference, the degree of M.D. upon Madame Kaschewarow, the first female candidate for this honour who had presented herself before them. When her name was mentioned by the Dean, it was received with an immense storm of applause, which lasted for several minutes. The ceremony of investing her with the insignia of her dignity being over, her fellow students and new colleagues lifted her upon a chair, and carried her with triumphant shouts through the hall. At this moment Madame Lucca, the prima donna, was espied among the audience, and such was the students' fickleness, that the lady doctor had to yield her elevated seat to the popular singer. The latter not only remained in undisputed possession of the extemporised throne, but was carried upon it to her carriage, while the new doctor had to find what comfort she could in her diploma!

SCOTLAND.

THE UNIVERSITIES.

DR. NEIL ARNOTT has given £1,000 to each of the Universities of Glasgow and St. Andrew's, for the endowment of scholarships in connection with experimental physics or natural philosophy. Dr. Arnett had previously given a similar donation to the Universities of Aberdeen and Edinburgh. He also lately placed at the disposal of the Senate of the University of London the sum of £2,000 to found a scientific scholarship in that University.

Magnificent endowments like these are greatly needed, and the Universities will ever be grateful to Dr. Arnett for his liberality.

THE LATE DR. JAMES BEGBIE.

Our obituary of to-day records a death that will be widely felt and deeply mourned. For nearly half-a-century Dr. James Begbie has practised as a physician in Edinburgh. Born in our city at the close of the last

century, educated at the High School and University, he graduated in Medicine in the year 1821. He was early associated, first as apprentice, and subsequently as assistant, with Dr. Abercrombie. Thus favourably introduced, he soon, by his own merit, and without any of the *prestige* of university connections, acquired an extensive practice. A thorough master of the science of his profession, careful and painstaking in his diagnosis, singularly excelling in his treatment of disease, fertile in resource, prompt and discriminating in his application of all known and available remedies, there was something in Dr. Begbie's presence and manner peculiarly attractive. His very entrance into the sick chamber, the manner of his approach to the bed-side, the gentleness and tenderness of his inquiries, inspired the patient with confidence. It was soon felt that there was more in him than the man of skill engaged in a professional pursuit—there was a brother of kindest human sympathy. The hand that so promptly, decidedly, and judiciously dealt with the bodily disease was seen and felt to be guided by a heart of exquisite sensibility. He entered many a family a stranger—he soon became the friend. We never knew or heard of any one in his profession who won so much personal attachment and regard.—*Scotsman*.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 163.)

Dr. M'CLINTOCK, by a process of reasoning of his own, based upon selected statistics, arrives at the conclusion, which I cannot at all agree with as what he terms "above suspicion," that 1 death in 134 is the right number to occur in parturition. And by another process, he increases the Registrar-General's rate, arrived at from data and sources at least equally "above suspicion" as his own. This he does by deducting one-fourth by his own arbitrary dictum from the Registrar-General's number, 171, for England and Wales, which reduces his ideal death-rate to 1 in 129. Dr. M'Clintock will excuse me, therefore, when I tell him that neither he nor the Registrar-General, were he innocent enough to adopt Dr. M'Clintock's calculation, would be justified, if their object be to give an accurate return of the deaths in childbirth, in deducting upon his abstruse *quaternionian calculation*, which throws Professor Hamilton's into the shade, one-fourth or other proportion for diseases proving fatal in parturition. Without entering into the subject as to whether these diseases may have been caused or called by parturition, there is one broad fact patent, that the fatality was determined by the complication of the disease with parturition, and non-sequitur, that any one of the cases would have proved fatal at all, and certainly not at that particular time, had not parturition been complicated with the disease, or it may be, produced the disease, and caused or accelerated the death. Therefore the Registrar-General's calculation of 197 mortality is strictly correct, and Dr. M'Clintock's deduction of a fourth is entirely untenable.

Dr. M'Clintock attacks my tenth proposition in his own ingenious manner.

He takes my general proposition and applies to it his own *literal*, not my *general* interpretation, when I state that puerperal fever "is not a disease observed to occur in small lying-in hospitals," and this, although I give the small hospital in which it occurs, with the date of its occurrence, twice over, once in page 302 and again in page 304. He then devotes a

whole page of statistics and argument to prove that I denied that puerperal fever *ever* occurs in small hospitals, and eventually winds up by admitting that my true meaning in the tenth proposition, which was as manifest as the sun in daylight to every eye but Dr. M'Clintock's, "*might* logically be inferred from the admission of the author that the poison of zymotic metria might be generated by any parturient female," and that this disease "is to be met with in the hovels of the poor and the chambers of the wealthier classes." Sir, I shall not designate such a line of discussion as I think it deserves. I ought, perhaps, to apologize for occupying so much of your time in refuting it.

But Dr. M'Clintock, descanting on the Waterford Lying-in Hospital, gives "five deaths as occurring in it from puerperal fever, with an average of only 115 annual deliveries." It would have only been justice to Dr. Elliott and the cause of truth, which we are at least ostensibly investigating, to have added that these five deaths from puerperal fever occurred in the Waterford Lying-in Hospital out of 3,469 deliveries, and extended over a period of thirty years, being a mortality of 1 in 681. A mortality that would quite satisfy me if I could bring it about at the Dublin Lying-in Hospital; aye, or one-half of it!

But, Sir, I regret I am not done with Dr. M'Clintock and the Waterford Hospital yet. In adducing these statistics from it, he falls into the very same blunder that, you will presently see, he attacked me for, and out of which he succeeded, by my enforced silence, in making such temporary capital. He fails, unintentionally of course, to distinguish accurately the two periods of the hospital, and, in place of giving the mortality by puerperal fever upon the long, or twenty-three year period, with its improved ratio upon the diminished number of beds, which he ought to have done in common justice to Dr. Elliott and the objects of his argument, *like* me he takes the whole period, but *unlike* me he does not give the results upon the improved period; of course his doing this was, as in my case, a mere slip of the pen in transcription. Let us see what the difference amounts to in the correct way of giving these results. We have seen that in Dr. M'Clintock's manner of proving the rate of mortality, the death-rate of the more crowded Waterford Hospital was 1 in 681; but in the correct and fair way of calculating it amounted only to 1 in 1,328. It will be perceived to prevent mistakes, as Dr. Elliott requires, we have put his calculation, not mine, in letters.

So much, Sir, for Dr. M'Clintock's purism in his own calculations, and his vaunted refutation of my tenth proposition, to refute which, he says, it were enough to cite the instance of the Waterford Lying-in Hospital. The Liverpool Lying-in Hospital is the next cited, but as he gives it a mortality of 1 per cent. it tells in favour of my position, although, as I have already said, I do not admit it as to be classed with the cottage hospitals. I only wish we could reduce the mortality of the Dublin Lying-in Hospital to 1 per cent.

The next instance adduced against the establishment of cottage hospitals is the South-Eastern, or Dr. Beatty's Lying-in Hospital. Dr. M'Clintock introduces his notice of it in these words—"I feel great satisfaction in appealing to the statistics of this little hospital, knowing they are worthy of implicit confidence." I confess honestly I cannot join in the great satisfaction he expresses upon this subject, and feel assured, as was the case in the great lying-in hospital, Dr. Beatty must have laboured under difficulties from the construction of his hospital that rendered it impossible to keep his mortality at a lower standard than 1 in 69. At all events, as I elsewhere stated, I admit no comparison between Dr. Beatty's hospital, with nearly 400 deliveries annually under one roof, and the cottage hospitals already alluded to, and to which we may now add the Killarney and South Dublin Union Hospitals; and be it remembered that these only afford an

approximate test of the principle of isolation, as in none of them has the principle been carried out to the full extent required.

The last case adduced by Dr. M'Clintock against my tenth proposition is the small Kingstown Lying-in Hospital. Dr. M'Clintock says that "the annual deliveries, not exceeding 90, it is in every point of view an *unexceptionable* specimen of a cottage hospital." Judging from its statistics, I should arrive at a very different conclusion, and as these are my only data for forming an opinion, I must say that I pronounce it in every point of view an *exceptional* specimen of a cottage hospital. When Dr. M'Clintock analyses on the strict philosophical principles laid down by Mill, as applicable to exceptions to general rules, the true explanations of the causes that render it exceptional, then I shall attach value to the exceptional case of the Kingstown Hospital, with its total mortality of 1 in 68, or of 1 in 114 from puerperal fever. In the meantime we must class it with the exceptional case of Ballarat to be afterwards alluded to, as adduced by Dr. Stokes, as a mystery, which, although unsolved, may not be insoluble.

Dr. M'Clintock, as well as several other of my critics, has called in question the statistics supplied by the General Registration Offices throughout these kingdoms. I am not here as the apologist of this department. Those indefatigable and distinguished men who direct and control this great department, one of the few scientific branches of the Executive in this country, stand too high by their labours and results to require me as their apologist. But, Sir, I must be permitted to express my dissent from and regret at the flippant and offensive manner in which this great organization of the State has been treated. Sir, I deplore it the more because I am old enough to recollect the difficulties we had in getting this great desideratum—the Census Office—established upon a fixed and permanent basis; the jealousies it excited, and the difficulties there were to bring our legislators to adopt it. It behoves thinking men to consider how far they are justified in breaking the faith of the public in so wise and so valuable a department.

For my own part, I totally disagree with all the slighting remarks that have been thrown out upon the statistical labours of, and results supplied by, the Registrar-General's Office. I rely upon the latter as the best information procurable upon the subject of statistics generally, and I have no doubt that, even admitting it to the fullest extent, that certain inaccuracies must creep into their calculations from accident, different views of seeing facts, or even from design, yet that these are counterpoised by their opposites and corrected by their analogues in such a manner as to render the total results as nearly correct as any human machinery, which necessarily employs an immense and varying agency, can accomplish it. I therefore accept the Registrar-General's statistics as, if not the best possible, at least the best possible with our present facilities, and feel myself quite justified in assuming them as the soundest attainable basis in the present discussion. Their very extent should render them unexceptionable to my critics, as they insist so much upon this element of proving statistical truths. I shall therefore say, that with the greatest deference to those of my commentators who have collected statistics of their own, bearing out their views of what should be the mortality of lying-in women, I shall prefer accepting the statistics of the Registrar-General, and his statement of what it actually is, to their selected figures, collected and marshalled to prove what it ought to be. This general statement will dispose of a host of those gentlemen's calculations who have favoured us with statistics of their own selection and procurement, but which are entirely at variance with those of the Registrar-General.

It will now be convenient to allude to another law that demands our attention and consideration. It is conveyed in the word habitat, which you will recollect is the subject of my

fourth proposition—one which has been the object of nearly as many attacks as my third; so many, indeed, that my belligerent critics must have looked upon it as the Malakoff of my position. They are right in so doing. So do I.

(To be continued.)

OUR CLUB.

THE last dinner of this season was looked forward to by the members of the Medical Club with more than usual interest. It was to be an epoch in the history of the Club, and the much-respected founder, Dr. Lory Marsh, was to occupy the chair. Most of the leaders of the Profession who were in town were there to welcome him and support him on the occasion, and Dr. Marsh also received the sympathy and good will of many who could not be in London that evening. In reply to the toast of "Success to the Medical Club," Dr. Lory Marsh made a full statement of its rise and progress. As the 700 members who owe to him the existence of the Club will feel deeply interested in his speech, we report it—contrary to our usual custom—in full. This we do the more willingly inasmuch as there must be many hundreds, perhaps thousands of the Profession who would like to join, but have not yet decided to do so. Dr. Lory Marsh's speech may be the means of deciding many such. He said:—

I may be permitted, and perhaps expected, to enlarge a little upon the subject of the toast of "Success to the Medical Club." The present may be looked upon as a sort of last dying speech and confession. It is the last occasion of our dining together during the present season, and it is also one in which I am especially called upon to confess to many shortcomings.

Whilst contemplating our future, it is desirable on such an occasion as the present, to take a backward glance at some of the objects sought to be accomplished by the establishment of this Club, and the means by which these objects are proposed to be carried out.

This Club was established to promote in every possible way harmony, union, and good fellowship between all branches of the Profession. It was designed, as far as such an institution could, to raise the social status of the Profession. Another, and perhaps more important object sought to be attained by the establishment of the Club, was to afford a ready channel through which the voice of the Profession might make itself heard in the corners of the State, upon all questions of a political character affecting its interests. Just as the Carlton and Reform Clubs represent the political opinions of the parties they are supported by, so the Medical Club was intended to represent the political interests of the Profession, as well as of science and art generally.

In the case of the Medical Club, politics would of course be regarded in the broadest sense, and not in any degree in the light of party politics. No matter what party may be ruling the destinies of the nation, there are always questions before the House, or want bringing before it, in which the voice of the Profession has a right to be heard in furtherance of its own and the public welfare.

There are not many medical members in the House of Commons, and a Club such as this is capable of rendering them great assistance. It may be regarded as the only truly representative body in the Profession, enrolling among its members, London, Country, British and Foreign, Army and Navy medical officers, all branches of the Profession, and in all quarters of the globe.

At present it is the nucleus of a vast organization, which must in time exercise a powerful influence on the future advancement of the Profession. Any ten members can call a general meeting, and take the sense of the Club upon any question which they may deem of sufficient importance to bring under the notice of the members. This rule has not yet been taken advantage of, but as our numbers increase it is hoped they will frequently be called together to discuss questions of a political and official character.

One man is comparatively powerless to make his opinions heard and felt in the House of Commons, but if he can get 700 others (and in time we would hope half as many thousands) to back up his opinions, no Government could altogether turn a deaf ear to his petition. In fact, as Sir William Fergusson remarked at the anniversary meeting, "it is impossible for such a number of men to combine together, without their acquiring more or less of a political existence." I have no doubt we should have had wiser legislation for the Profession in years

gone by, if the Club had been in existence. Should the Government next year propose to bring in an amended Medical Reform Bill, I hope it will receive such an amount of attention by the Club, as to carry its impress upon it, as a measure truly representing the opinions of the whole Profession. I think we shall be able to render the Legislature very material assistance in attaining this most desirable object.

The Club is based upon such a broad and liberal foundation, that no gentleman need be excluded from it, and, once admitted a member, he is privileged to meet on a common platform with the leading men in the Profession. This is an advantage impossible of attainment in any other society. It was one thing to sketch out such a commonwealth as our Club proposes to be, and another thing to carry it into effect. I am sure every member felt in adopting the name "Medical" we were to a certain extent responsible that the honour and reputation of the Profession should be in no degree tarnished by any act of ours. We had, moreover, to deal with a class of men whose means could bear no comparison with the wealthy merchant or the large landed proprietor; we had also to provide for a class of busy, active, hard-working men, amongst whom the class of what may be called "Club lounger" could not be found. Time means money, and money means hard work. Our members also were very widely scattered, and few could be found to take an active part in the management of the affairs of the Club. Many had been the victims of bubble schemes got up to enrich the pockets of the few at the sacrifice of the funds of the subscribers. All stipulated before joining the Club that they should be held legally free from any pecuniary liability (beyond their subscription) in carrying on the Club. It was with these limitations and restrictions the Committee undertook the responsibilities of office. Acting under the advice of counsel, they found there was no possible way of carrying out the principle of non-liability on the part of the members but by handing over the funds of the Club to some individual to conduct it for them. By so doing, the individual selected became solely responsible for all liabilities incurred in the conduct of the Club. They did me the great honour to appoint me to that important post—and here I would offer my humble apologies for the very imperfect manner in which I have discharged the duties of the trust reposed in me. It would be simple affectation to deny that I have tried to do my best; but the task of organizing the Club was much more difficult than I expected; the correspondence so very voluminous, and extending over such a wide range, that I often found myself in a perfect maze of difficulties, from which, I fear, in too many instances, I have not been able to escape without committing many blunders. The members have shown great leniency towards me, and have ever been ready, in the most generous manner, to make allowance for all my mistakes, for which I owe to one and all a lasting debt of gratitude. The funds at my disposal have been, too limited to enable me to do all I could have wished in the development of the Club. As we become more prosperous, and our numbers increase, we shall, of course, be enabled to enlarge our sphere of operation. I hope in time the Medical Club will take a position equal to any Club in London. I shall not be satisfied until we have secured a building that shall be worthy of the Profession, and then I will gladly resign my trust into the hands of those from whom I received it. Through many difficulties, and often much labour, I am happy to say we can now begin to see in the distance that success for which we have all so anxiously and so incessantly striven. In a few years we hope the reputation of the Club will be established, and that it will become an object of ambition on the part of candidates to be enrolled amongst its members. For the present our motto must be, "Work and wait; there's a good time coming." Some may be inclined to question whether the principle upon which the Medical Club is established is capable of being successfully carried out. To this question there is no difficulty in finding an answer in the experience of some of the oldest and best Clubs in London, such as White's, Brooke's, Boodle's, &c. I am inclined to think the modern Club has lost much of the charm, and many of the advantages of the older Clubs. Formerly men did not combine to erect stately edifices, in which each member was an unit of a large society, using it simply for the purposes of selfish enjoyment. They combined, as we have done, to cultivate and enjoy each other's society at the least possible expense, and to unite for the furtherance of certain principles in which all are alike interested; with the exception of the politica

Clubs, the magnificent buildings we see around us, with their princely incomes, appear to exist simply for the supply of the personal wants and gratifications of individual members. Our personal wants are few, and limited in extent; but, like the political Clubs to which I have alluded, we have combined together to cultivate social intercourse between the members of the Profession, at home and abroad, and to advance, by every possible means in our power, the interests and prosperity of the Profession we represent.

Correspondence.

THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the constitution of the Medical Council is engaging the attention of medical reformers, and as every member of the Profession is bound to assist in any movement calculated to improve the position of medical men, it may not be out of place for me to offer a few remarks in support of the views which I entertain respecting the constitution of the Council, and which have been adopted by the Cork Medical Protective Association, at two of its annual meetings.

In the first place let us inquire what are the objects for which a Medical Council was established? They are, to secure uniformity of education and qualification, to secure to the Profession its rights and privileges, and to protect the interests of the Profession and the public.

If this be a legitimate programme for the General Council of Medical Education and Registration of the United Kingdom, I think every impartial observer will admit that the present Council has been a lamentable failure; that it has given no adequate return to the Profession or the public for the money paid by the former, and that, if we are to judge of the future by the past, there is no likelihood that any good will result from a Council consisting of gentlemen who hold the most opposite opinions on every subject that can come before them, who represent rival Universities and Colleges, and who meet only once a year to discuss the multifarious topics that should engage their attention. To me it appears quite clear that a Council composed of such heterogeneous elements will never have unanimity in its proceedings, and I believe it is impossible that twenty-four gentlemen selected from different parts of the United Kingdom, and meeting once a year in London, can have sufficient time to consider the many important questions connected with medical reform. During the eleven years that the Council has been in existence it has done nothing worth mentioning, except to publish a Pharmacopœia, and no stronger proof of the cumbrous nature of the machinery at its disposal could be given than the fact that it took nine years to produce this work.

No doubt the Medical Act is defective, and requires amendment, and the Council's inability to do anything useful may be partly attributed to this, but no alteration in the wording of the Act of Parliament will make it thoroughly efficient unless there be a radical change in its constitution.

The Medical Council is an administrative body, and I believe its representative character interferes with its administrative powers, for while it remains a representative body it never will be an independent body, as each member is expected to consult the interests of his constituents, irrespective of the general good; and as the experience of the last ten years shows the utter impossibility of reconciling the conflicting interests represented in the Council, there must be a total want of such unanimity as is essential to the due execution of its administrative functions.

It appears to me, then, that there are three objections to the Council as at present constituted:—1. It consists of too many members. 2. It only meets once a year. 3. It is a representative body.

The Council consists of twenty-four members—six nominated by the Crown, and the rest returned by the different corporations, and the mode of transacting business is to divide those twenty-four members into committees and sub-committees, the report of each committee then becomes the subject of debate at a general meeting, and thus each Session is wasted in rhetorical display; whereas a Council of one-fourth the number sitting permanently and independent of the licensing bodies could devote its undivided attention to the consideration of

practical details, and would be always accessible to the Profession and the public.

To remedy this unsatisfactory state of things, it has been proposed that the registered practitioners should be allowed to elect representatives on the Council. Now, it seems to me that this arrangement would make matters much worse, it would add another to the many discordant elements that already exist in the Council, it would increase the amount of talk, protract the debates, and enhance that acerbity of feeling which has so often disturbed its proceedings.

Dr. Prosser James proposes that the representatives of the corporations should be elected by the members or graduates, instead of by the governing body, it is contended that by thus extending the franchise the Council would become more popular; but what we want is not to popularise the Council, but to make it more efficient, and I doubt very much if this plan would have the effect of increasing its efficiency, as each member would still look upon himself as the representative of some particular corporation, whose interests he would consider paramount to all others, while the objection still remains that no body of men, however eminent, sitting for so short a time annually, can promote any useful measure of reform.

The proposal which I advocate, and which has been approved by the Cork Medical Protective Association, is to abolish the Council and appoint a Medical Board, similar to the Poor Law Board; this Board should consist of not less than three, and not more than six members. They should sit permanently, and be ready to receive suggestions from the corporate bodies, the various Medical Associations, and even from individual members of the Profession. They should be empowered to enforce their own regulations, and institute public prosecutions, and one of their principal objects should be to assimilate the courses of study for degrees and diplomas in the different Universities and Colleges.

An objection may be raised to this plan, on the ground that there should be no taxation without representation, and that, if adopted, those who pay for registration would have no voice in the election of members; but my answer is the representative system has been tried and found wanting, after ten years it has been pronounced a complete failure, and the proposals of Dr. James and others only refer to an alteration in the mode of election to the Council, instead of some radical change in its constitution.

Enlarging the constituency while the Council retains its representative character will not secure unanimity in its proceedings, and with a Council constituted like the present, it is out of the question that we can ever get a uniform standard of education; it is useless to expect the suppression of quackery or the reform of the many abuses that medical men have to complain of.

The lunacy laws, skilled evidence in courts of justice, the laws of hygiene, &c., would form fair subjects for discussion in a Medical Council, if its object be to protect the interests of the Profession and the public.

How is a Council sitting ten days once a year to consider all those topics. Does any member of the Profession feel his position improved since he became a registered practitioner?

It is true that some medical grievances have been redressed, but their redress was owing to the action of the Medical Protective Associations, and not to the Medical Council.

An efficient Medical Council should possess the characteristics of *unanimity*, *permanence*, and *independence*. Its deliberations must be marked by harmony to inspire respect and confidence, it should sit permanently to become acquainted with medical grievances, and to master the details of the various questions that may arise from time to time, and it should be independent of all the licensing bodies, so as to secure freedom of action and give weight to its decisions.

Every member of an Administrative Board should be free and unshackled, *nullius in verba magistri*, and it is only by divesting the Council of its representative character, by reducing its numbers, and making it independent of all the licensing bodies, that we can secure an impartial administration of the law and hope for a proper supervision of medical interests.

I am, Sir,

Your obedient servant,

D. B. O'FLYNN, A.M., M.D.

Carrignavar: August 17, 1869.

ON THE CAUSATIVE AGENCY OF THE SKIN AND LIVER IN THE INDUCTION OF PHTHISIS AND OTHER SCROFULOUS MALADIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Are we really, in regard to the treatment of phthisis, like the blind Cyclops in the Cave of Ulysses?

Is the Profession still, as Dr. Luther's article of the 11th inst. would lead one to believe, groping for a specific? Dr. L. wonders that the exhibition of lemon juice has never been tried in phthisis, and proposes to experiment on the first unfortunate patient he meets with well-marked phthisis. Before doing so I trust he will look at Thomson's "London Dispensatory" page 353, where he will find that its continued use hastens the progress of phthisis. He might also read Liebig's "Letters on Chemistry," page 428. Before building up a theory on the glycogenic function of the liver, it would have been well for him to have in his recollection that the experiments of Pavy have shown the glycogenic function to be a myth. Dr. L. speaks of scrofula as if identical with tubercle, which I think he would hardly have done had he heard the lectures of Dr. Reginald Southey, delivered at the College of Physicians, and reported in the *Medical Press and Circular*, May, 1867.

A true appreciation of the pathology of the disease will be the best guide towards its treatment; by comprehending the mode in which excessive acidity is produced in phthisis, he will seek his specific by the light of science rather than wait for empiricism to aid him with a wandering gleam. In the "Rational Treatment of Consumption," by Dr. Mulvany, *vide* MEDICAL PRESS AND CIRCULAR, April, 1868, &c., he will find potassæ permanganas recommended as a curative agent in incipient phthisis, on physiological, philosophical and chemical grounds. In Dr. McCormac's book on Consumption, he will find the *causa causans* so lucidly described that it is a matter for wonder and regret that the disease should ever be treated empirically.

I am, Sir,

Your obedient servant,

A CONSTANT READER OF THE MED. PRESS & CIR.

Portsmouth, August 18, 1869.

A NEW METHOD OF EXTENSION IN FRACTURES OF THE FEMUR AND IN COXALGIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read several communications in your paper upon extension in fractures of the femur by means of the weight and pulley, I am induced to bring before the notice of the Profession the splint described below, which is at once simple in construction and easy of application.

Extension by means of the weight and pulley, though undoubtedly possessing many advantages, is, I think, open to the following objections:—

Firstly, the difficulty of its application;

Secondly, the unavoidable inconvenience and uneasiness it causes to the patient;

Thirdly, the extension not being made approximately from either end of the injured part.

The great desideratum, then, is to get a splint easy of application, causing as little inconvenience and pain to the patient as possible, and to make extension and counter-extension as close to the injured parts as we possibly can, at the same time keeping up a constant equable and easily adjusted pressure.

Some six weeks since I made the splint, which I think possesses the above advantages. I have had no opportunity as yet of seeing it applied to fracture of the femur; but in a case of coxalgia, under the care of Mr. Croly, who kindly allowed me to apply it, the results have been such that its application to fractures of the lower extremity, where permanent extension may be required, will, I have no doubt, be successful.

It is made in the following way:—

An ordinary Liston's splint of the size and length required is taken and cut across opposite to the injured part, (A and B.) A piece of wood, C, about two feet long, and from two to three inches wide, and half an inch in thickness, is screwed in the middle of B, so that it may project about eighteen inches from its lower end.

To the lower part, A, are screwed two slips, D, D, about eighteen inches long, with one edge of each planed off so that the slip C may slide between them in a dovetail groove. A

small brass or iron plate, E, with three or more stubs projecting from it, is screwed to the upper end of the two slips D D, so that the slip C may slide freely under it. To the lower end of C is screwed a similar plate, F. An India-rubber doorspring or some rope India-rubber is taken and cut into six or eight inch lengths, and to either end of each wire loop is attached. One (G) or more of these are stretched from the upper to the lower plate. On contraction the two portions of the splint are forced asunder with a tension proportionate to the number of springs applied. A light tin case, H, covers the working part so as to allow a bandage to be applied. The splint is adjusted like an ordinary Liston, extension being made from the injured part downwards by means of adhesive plaister on the American principle, counter-extension being made by means of the perineal band, assisted by adhesive plaister from the injured part upwards. If the fracture be high up, the perineal band must be dispensed with, as it would probably throw the lower end of the upper fragment outwards, the counter extension in that case may be made from the opposite thigh by means of a good fitting collar. The splint being thus applied the India-rubber springs are put on, the tin case is placed over them, and a bandage applied from the foot to the upper end of A, securing it to the lower portion of the limb, another bandage is applied round B, securing it to the upper portion of the limb and body.

Scored splints, &c., may be applied as usual.

I am Sir, yours faithfully,

F. W. FURNELL,

Resident City of Dublin Hospital.

Medical News.

UNIVERSITY OF LONDON.—The following are Lists of the Candidates who have passed the recent Honours Examinations:—

FIRST M.B. EXAMINATION, EXAMINATION FOR HONOURS. ANATOMY.

FIRST CLASS.—Ernest Alfred Elkington (Exhibition and Gold Medal), Queen's College, Birmingham; Henry Edward Southee (Gold Medal), Guy's Hospital; Ebenezer Rust Edger, B.A., University College; Thomas Crawford Hayes, B.A., Dublin, King's College (equals).

SECOND CLASS.—James Barry Ball, University College; Thomas Jones, Guy's Hospital.

PHYSIOLOGY, HISTOLOGY, AND COMPARATIVE ANATOMY.

FIRST CLASS.—Alfred Henry Carter, University College.

ORGANIC CHEMISTRY, AND MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

FIRST CLASS.—Henry Edward Southee (Exhibition and Gold Medal), Guy's Hospital; Thomas Jones (Gold Medal), Guy's Hospital; Francis Warner (worthy of a Gold medal), King's College; Joseph Theodore Ingoldby, Guy's Hospital; Ernest Alfred Elkington, Queen's College, Birmingham.

SECOND CLASS.—Thomas Crawford Hayes, King's College; William Barnett Burn, St. Bartholomew's Hospital; William Ward Cart, University College (equals).

MANCHESTER ROYAL SCHOOL OF MEDICINE.—Award of Scholarships and Prizes, Session 1868-69:—Third year scholarship, value £20, W. A. Patchett; second year scholarship, value £15, C. Holmes. First prize, value £5 5s., H. W. Webster; second prize, with extra value, £5 5s., H. Reston. First year, value £10, E. Bishop. First prize, value £5 5s., C. L. Smithard; second prize, value £3 3s., H. J. Price; third prize, value £2 2s., A. M. Edge.

APOTHECARIES' HALL.—At a court of examiners, held on Thursday, the 26th ult., the following gentlemen, having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries, viz.:—Messrs. M. D. Murphy, Cork (Dublin School of Medicine); T. J. Preston (St. Mary's Hospital); A. E. Schmidt (Guy's Hospital); H. J. Sharpe (St. Bartholomew's Hospital); and H. J. H. Vines, Reading (St. Mary's Hospital). And at the same court the following passed the primary professional examination, viz.:—Messrs. E. C. Ling, (Middlesex Hospital); T. P. Stephens (Guy's Hospital); and H. G. Turner (Guy's Hospital).

INCREASE OF PAUPERISM.—The official return issued on Friday last, shows that the number of paupers (except lunatics in asylums and vagrants) in receipt of relief in England and Wales on the last day of the fourth week of June, 1869, was 932,218. The corresponding numbers in the previous year was 922,563, showing an increase against the present year of 9,665 or 1.0 per cent.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

Dr. BALTHAZAR FOSTER, Birmingham, will please receive our best thanks.

Dr. ALEXANDER LEADMAN, Leeds.—It has not yet come to hand.

Mr. STEWART.—The twelve copies of August 25 have been sent to the address given.

ERRATUM.—By a printer's error Helminthology, communicated by G. Gaskoin, Esq., was spelled with an *z*, thus Herminthology.

Dr. EDWARDS CRISP, Chelsea.—We have, on several occasions, given space to your letters, and we have now no desire to depart from our rule of strict impartiality. We can but repeat what we have before said on this question—which was considered closed more than twelvemonths since,—that if Dr Crisp or any other gentleman can give any tangible proof of a mal-adjudication of the Carmichael Prize Essays, the same shall have due publicity in our columns, otherwise, we can take no notice of any further communication upon the subject.

L.R.C.P.E.—The papers appeared in the MEDICAL CIRCULAR before its incorporation with the MEDICAL PRESS. The facts which they set forth are, we believe, accurate, and they are certainly instructive, and we have no reason to discredit the source from which they come.

COMMUNICATIONS, Enclosures, &c., received from Mr. Holthouse, Westminster; Mr. F. Geere, Brighton; Mr. Tichborne, Dublin; Dr. Liveing; Mr. Street; Dr. Carpenter, London; Mr. Powell, Manchester; Dr. Luce, Glastonbury; Dr. George Lade, Kings' Lynn; Mr. J. T. Jones, Weedon; Mr. J. Lafarelle, Colshill; Dr. Edwards Crisp, Chelsea; Mr. Bingham, Greenborough; A Governor of Queen's College, Birmingham; Dr. McCall Anderson, Glasgow; Dr. Dunbar, Glasgow; Dr. Jackson, Beeford; Dr. Embleton, Newcastle; Dr. Foster, Birmingham; Dr. Leadman, Leeds; Dr. Crafter; Mr. Squire, Dr. Saffen, Stoke Newington; Dr. Drysdale, London; Dr. Waring-Curran, Sutton; Mr. Ross, Glasgow; Mr. Stewart, Edinburgh; Dr. Bennett, Beechgrove; Mr. Langley; Mr. Harben; Dr. More Madden, Dublin; Mr. W. Legge, Alfreton; Mr. J. Lewellyn, Cardiff; Dr. Finucane, Kingstown; Dr. Foot, Gortmore; Dr. Johnston, Kilkenny; Dr. Bewley, Clara; Dr. West, Dublin; Dr. Lynn, Sligo; Dr. McManus, Ballymahon; Royal Dublin Society; Dr. Benson, Dublin; Dr. Fitzpatrick, Maryborough; Dr. Torney, Dublin; Dr. Atkin, Virginia; Dr. Pollock, Blackrock; Dr. Knight, Clowes; Dr. Carte, Kilmainham; Dr. Richardson, Dublin; Dr. Hunt, Dungarvan; Dr. Flanagan, Tuam; Dr. Sandman, Cork; Dr. Walsh, Dublin; Dr. Sale, Kilmegall; Dr. Anthony, Dungarvan; Dr. Ross, Ballymena; Dr. Deverell, Ardglass; Dr. Morris, Deddington; Dr. Lory Marsh, Nottingham; Dr. Sanders, Edinburgh; Mr. Kirkby, Sheffield; Dr. Nicholas, Wandsworth.

APPOINTMENTS.

HALL, Dr. Egerton F. M.D., St. Andrew's, Medical Officer of the Prescot Union, Lancashire.

HARRIS, Dr. James Smith, L.K.Q.C.P. Irel., and L.M., M.R.C.S. Eng., Medical Officer of the Isle of Thanet Union, and Medical Officer for the workhouse.

SCOTT, Dr. Henry Thomas, Medical Officer for District No. 3 of the Croydon Union.

ADAMS, Dr. Thomas Rutherford, M.D. Brussels, L.R.C.P. Lond., Public Vaccinator for Croydon, Addington, and Sanderstead.

NUNN, Dr. George R., L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., Medical Officer for the Lyndhurst and Minestead District of the New Forest Union.

PRESTON, Dr. Eyre Frederick, Medical Officer of the Kilkeel No. 1 Dispensary District of the Kilkeel Union, County Down.

Lecture.

ON THE USE OF THE FORCEPS IN MIDWIFERY PRACTICE.

DELIVERED IN THE

ROTUNDO DUBLIN LYING-IN HOSPITAL.

By THOMAS MORE MADDEN, M.R.I.A.,

Assistant Physician to the Hospital.

(Continued from page 182.)

THE cases in which we resort to the application of the short forceps are daily becoming more numerous; and I know of hardly a greater improvement in the practice of any branch of our Profession than has resulted from the more frequent and timely employment of the midwifery forceps in those cases which require its use. The long forceps being less commonly required, and more difficult in its application than the short instrument, I shall, before speaking of the former, in the first instance point out the cases suitable for the forceps more generally employed, and describe the manner in which it should be used.

The most frequent cause of difficult labour requiring the use of the short forceps is inertia of the uterus. Thus, out of thirty-eight cases in which I have been obliged to apply the forceps, this measure was necessitated by inefficient uterine action in twenty-two cases, in all of which the labour was delayed in the second stage by this cause alone, the pelvis being sufficiently roomy, and the soft parts dilatable.

Before the forceps are applied the os uteri must be fully dilated, or at least dilatable. Denman's rule was that "the head of the child should have rested for six hours as low as the perinæum before the forceps are applied."^(a) This rule is quoted with a qualified approval

by the author of the "Dublin Practice of Midwifery," which is still the favourite text book in this country. Dr. Murphy is a great advocate for non-interference, be the second stage however long, and however slowly the head may advance.^(a) Dr. Gooch says that the forceps should not be applied until the head has been for twelve hours stationary on the perinæum. Dr. Ramsbotham, who is copied by other recent writers, fixes the time which should elapse after the dilatation of the os before the application of the forceps as four hours in ordinary cases.^(b) No rule, however, as to the time which should elapse after the os uteri is dilated before the forceps should be applied, is of any practical value. One patient will suffer as much in one hour as another will in twelve, and therefore the only point to be considered is the actual condition of the mother and that of the child, and the particular circumstances which in each case render artificial delivery necessary.

The dangers of undue delay in affording instrumental assistance to the efforts of nature to effect delivery in cases of difficult labour once the os uteri is fully expanded, and the soft parts sufficiently dilated, are, in my opinion, as serious as those which are produced by needless hasty and meddlesome recourse to the forceps, a practice which no one can reprobate more than I do. The lives of both mother and child are endangered by undue protraction of the second stage of labour; and the fact is unquestionable that after long protracted labours the proportion of deaths from metritis, puerperal peritonitis, and other diseases to which women are subject during convalescence after delivery, is much greater than it is in cases in which labour has terminated within the natural period. This fact has been conclusively established by Drs. Johnston and Sinclair's "Report of the Practice of the Rotunda Hospital,"^(c) as well as by Dr. Churchill's statistics,^(d) and the opinions

(a) Maunsell's "Dublin Practice of Midwifery." P. 124.

(b) Ramsbotham, "Obstetric Medicine and Surgery." P. 245.

(c) Drs. Johnston's and Sinclair's "Practical Midwifery." P. 35.

(d) Sir James Simpson's "Obstetric Memoirs," Vol. i. P. 533.

(a) Denman's "Midwifery." P. 275.

of Sir James Simpson,^(a) Dr. Tyler Smith,^(b) Dr. T. Beatty,^(c) Mr. Steele,^(d) and other recent writers.

In cases of difficult labour, if the violent, painful, and, at the same time, powerless expulsive uterine efforts of the second stage be permitted to continue too long unassisted, a state of inertia will probably intervene, the pains gradually becoming weaker, it may then become impossible to re-arouse the worn-out contractile power of the uterus; and this inertia may prove fatal when too late the necessary assistance has been given, by resulting in uncontrollable flooding.

Rupture of the uterus is another occasional consequence of delay in the second stage of labour. The uterine walls being torn through by the forcible and spasmodic action which a little assistance afforded at the proper moment might have directed and aided in effecting a safe delivery. Nor are these the only evil consequences of that morbid dread of instrumental assistance in midwifery cases under any circumstances which still lingers in the minds of some practitioners. Lacerations, contusions, inflammation, and sloughing of the recto-vaginal or vesico-vaginal septa, or of both, are too often the result of the long-continued pressure of the child's head on the soft parts in cases of protracted labour; and I have seen deplorable cases of this kind resulting from the neglect of applying the forceps.

The child, too, is as much endangered as the mother by undue delay in the second stage of labour. The foetal head suffers from the protracted compression to which it is thus subjected, and there is a strong probability that the uterine contraction acting directly on the child after the rupture of the membranes may exercise a great degree of pressure on the child's body, and by compressing the funis cause its death. This danger to the child would, in my opinion, not only justify, but demand our immediate recourse to the forceps as soon as we have any reason to apprehend danger to the child from the further protraction of the labour. It surely can need no argument to demonstrate the fact that it becomes our unquestionable duty, when we believe that the child's life is in danger, to interfere the moment it becomes possible to do so, and to rescue the child from perishing in the womb, as well as to save the mother's life. The practitioner who, under such circumstances, would hesitate to deliver at once with the forceps would incur, as I believe, the same moral guilt that would rest on a man so void of humanity as to pass by a drowning fellow-creature whom he might have rescued from death by stretching forth his hand.

A very slight degree of disproportion between the head of the child and the passage through which it has to pass during labour is sufficient to render parturition difficult. But in the majority of these cases the natural powers are able to overcome the difficulty thus created, the child's head being compressed and altered in form, often to a very remarkable extent, so as to accommodate itself to the size of the passage through which it is forced during labour.

Every student of midwifery who has any practical experience at the bed-side of lying-in women must be fully aware of the extraordinary degree of pressure the foetal head will bear so as to alter its form completely during a protracted labour without the least injury, and how rapidly it will recover its natural shape often after a couple of days from being elongated to an almost inconceivable degree becoming round again.

Slight disproportion in size between the mother's pelvis and the child's head was the cause which led to the use of the forceps in five of my cases; and even a more considerable degree of disproportion may be successfully treated by this operation. It should not be

rashly concluded that because a woman has some pelvic deformity, and because her medical attendants in her previous labours resorted to the perforator and crochet, that you must abandon all hope of saving the child's life. On the contrary, a very short time ago I attended a woman who had been delivered by the perforator and crochet on her two previous labours, there being some flattening of the curve of the sacrum, but who now gave birth to a well-formed living child at the full period by the natural efforts. Cases have been recorded in which living children have passed through a pelvis scarcely measuring three inches; ^(a) so that even a considerable degree of pelvic deformity may admit of the successful application of the forceps.

In such cases it may be a matter of extreme difficulty to move the foetal head with the forceps, notwithstanding that it is accurately adjusted, and all the powers of the instrument, so far as compatible with safety, have been fully applied. It may happen that the accoucheur's efforts have been thwarted by rigidity of the soft parts, or that the child's head is not yet sufficiently moulded and compressed by the natural efforts—in other words, that the forceps were applied too soon; and if the instrument be withdrawn for a time we may again introduce it with perfect and facile success. If, even then, when the practitioner knows that no impediment is offered by the soft parts, and that the head has had due time to accommodate itself to the pelvic cavity, he finds it impossible to effect delivery; still let him not be disheartened, and, by abandoning the forceps, take away the only chance that remains for the child's life. On the contrary, let the forceps be again withdrawn and again reapplied, but in another position, and again in another, as long as is compatible with the safety of the mother; and, in the great majority of cases, he will thus succeed where a less patient practitioner would have fail.

The application of the forceps in certain diseases of the heart and lungs, where danger may be apprehended from the protraction of the violent expulsive efforts of the second stage, is sanctioned by the high authority of Dr. Churchill. The forceps may also at once be resorted to if, from any cause during the second stage of labour, the pulse rises above 100; if the abdomen becomes tender on pressure; if super-pubic pain, premonitory of rupture of the uterus, occurs; or if symptoms of exhaustion or prostration, with excitement, manifest themselves, no matter how short a time the labour has continued, or if the sounds of the foetal heart become weak, and if the cranial bones overlap much. The employment of the forceps in cases of complex labour is a subject I shall reserve until we come to speak of the long forceps.

It is laid down as an axiom by most writers on midwifery, that the forceps is intended only for cases in which the child is alive, and should never be employed to deliver dead children with. I cannot agree with this rule, however. We can have no certain knowledge as to the child's condition until it is born, as all the means of diagnosis at our command, including the stethoscope, are very fallacious; and we would not, I think, be justified in relying so far on them as to do anything that prevents the chance of saving the child's life. I have, more than once, seen a living child delivered by the forceps in cases where no sound of the foetal heart could be detected, even by most experienced auscultators, and where the cranial bones were loose and overlapping, and the discharges fetid and discoloured.

(To be continued.)

THE CONSIDERATION OF RITUALISM, WITH REFERENCE TO ITS INFLUENCE ON INSANITY.*

By J. T. SABBEN, M.D.

MR. PRESIDENT AND GENTLEMEN,—

It is my intention in this paper to bring under your consideration a subject which I believe to be of the utmost importance to us in our special branch of medicine.

The daily spreading influence of Ritualism, and its injurious effects on society, call forth some observations which, I feel sure, you will not consider out of place in this meeting.

Ritualism, at the present time, is evidently one of the most prominent causes of insanity in the middle ranks of life; within the last two years I have had under my care several cases of mental derangement caused by it, and have selected those of the most importance, which I intend bringing under your notice.

From my own observation, and so far as I have been able to ascertain, it appears that the young are more attracted by it than those of mature age. In a church I attended a few Sundays ago, among a congregation of about 500, consisting chiefly of boys and girls, only one grey head was to be seen. The places of worship have also so largely increased in number, that in some parts of London they are to be found within a stone's throw of each other, rendering both choice and position agreeable to its followers.

It is not my intention to enter upon what would approach a philosophical discussion on the religious bearings of Ritualism, but simply to confine myself to its morbid influence, as shown in the following cases:—

The first case is that of a clergyman of the Church of England, aged 34, who came under my notice last April twelvemonth. He had been in holy orders seven years; when I first saw him he was suffering from acute melancholia with strong suicidal tendencies. He was in a weak state of bodily health, and refused food. His chief delusions were that his brother priests and different members of the congregation had control over his mind that they knew his thoughts long before he was conscious of them himself.

The previous history of this case is as follows:—He was educated at a grammar school, and graduated at Cambridge. When ordained, he was licensed to a small church in the country, where he remained two years. He afterwards took a curacy in a Ritualistic church in London, living alone in apartments.

For the first three years he was most regular in his correspondence with his friends, who lived some distance in the country, when it was noticed his letters became less frequent, until at last he ceased to write at all. His friends receiving no tidings became alarmed, and proceeded to London, where they found him in the most wretched condition, sitting writing a sermon. On his father and sister entering the room, he simply bowed, not showing the slightest sign of affection; after they had been with him some minutes, he jumped up, rushed towards the window, exclaiming aloud and in great anger "that he knew that several clergymen (mentioning their names) were aware of his existing thoughts," then, turning to his friends, told them that their presence defiled him, and opened the door for their departure. The person with whom he resided informed the father that he had been in this state for some months, seldom taking his meals, and very often not going to bed more than twice a week, his nights being chiefly spent in prayer. The first service in which he took part commenced at 8 in the morning, the whole of the day being occupied in visiting different institutions connected with some Brotherhood to which he belonged. In the evening, when not engaged at his own church, he would go long

distances to attend others. This gentleman remained in the condition above mentioned for ten months, when he quite recovered, and after a short sojourn at the sea-side, returned, I am sorry to say, to his previous Ritualistic persuasion.

The second case is also that of a gentleman (J. W.), who came under my notice on December 9th, 1868. It was about 2 o'clock A.M. when I first saw him. He was then suffering from an attack of acute mania, and required five attendants to hold him, although, on examining him, he was found to be in a very emaciated state. He continued in this excited condition up to December 22nd, when he became quieter, even so much so that he walked about the grounds with one attendant; while in this quiet state he was more coherent in his conversation, but constantly referring to the religious ceremonies with which he had previously been connected, and would spend the greater part of the day in offering extempore prayers.

January 8th.—Acute symptoms having come on again, he remained in a raving state until the 14th, when he became calm and collected; having quite recovered from this attack, he continued comparatively well for a period of six weeks, after which time he suffered from relapses about every fortnight, each attack lasting two or three days; this went on until June 6th, when he became gradually better, and has remained well up to the present time, August 2nd, 1869.

The previous history of this case is as follows:—He was educated at Brighton College, and left there at the age of seventeen. He then returned to London, and entered a merchant's office in the city; for the first three months after leaving Brighton, he attended a Sunday-school in the parish where his friends resided, for the purpose of teaching the children. About this time his friends discovered that he was in the habit of going to "Ritualistic churches," and that his visits to the Sunday-school had become very irregular. His manners were considerably altered, he was very sullen, and would not join in any family amusements, or enter into secular conversation. His office hours were from 9 A.M. to 4 P.M., during which time he would make various excuses to get away, so that he might attend service at some Ritualistic church in the neighbourhood. He always rose at 5 in the morning, spending the interval until 8 A.M. in prayer, attending service before going into the city, and again in the evening on his return. He would pray for two hours before going to bed, and on several occasions was heard by his friends praying in the night, often falling asleep from sheer exhaustion.

Some of his evenings were spent with what are termed "Brothers," in going about to the different "Homes." He kept all the fast days with great rigour, and has been known to go for five days with nothing but bread and water for his diet.

The third case is that of a lady, aged twenty nine (M.K.), who came under my notice May 29th, 1868. She was in a very feeble state of bodily health, and suffering from acute melancholia; refused food, and was obliged to be fed artificially. Her chief delusion was that the souls of several persons had been given into her care, and that she must pray day and night to save them from destruction, stating, in her calmer moments, that the charge had been allotted to her when attending the Communion by one of the priests of her own church. She would spend the whole day in prayer, and when alone would hold imaginary conversation with spirits; she remained in this state for several weeks, and since then has been gradually improving.

The history of this case is, so far as I have been able to ascertain, as follows:—The patient was brought up in the Protestant religion, and educated in a boarding-school, where she remained until her eighteenth year. She lived with her friends until she was twenty-one, when she married a young officer in the Indian Army, went with him to India, residing there seven years, where she had four children, her husband died very suddenly, after his

* Read at the Annual Meeting of the Psychological Association at York.

death she and her children came to England and lived with her friends. For several weeks she kept quite in seclusion, feeling deeply the loss she had sustained. At this time she was persuaded by a friend to attend a Ritualistic church in the neighbourhood, which she did for three or four months, when it was noticed by those about her that she began to neglect her children, and would not allow them to be with her for more than five minutes a day. During this period she attended services from morning till night, starving herself on certain days in the week. This continued for some little while, when a further change for the worse took place, she became extremely slovenly in her dress, and would not allow herself time for even washing her hands, leaving her home for two or three days and wandering miles away, walking the whole distance to convert, as she said, the souls in her charge.

On several occasions she was found in the middle of the night, kneeling on the steps of the Ritualistic church she attended, in the attitude of prayer; soon after this she was found footsore in a wretched hovel on one of the commons, and her friends having naturally become very anxious, took immediate steps to place her under proper care.

The last case that I shall read is that of a young gentleman, aged nineteen, who came under my notice so recently as within the last month. He was suffering from acute melancholia, his delusions being that his father was to be murdered for his (the patient's) sins. He was in a very exhausted state of bodily health, not having taken food for four days.

Previous history.—He lived with his parents in a small provincial town, until he was sixteen, when they went to reside in London, he entering the University, where he studied up to the time of his attack of insanity. Soon after his arrival in London, he took great interest in the Ritualistic churches, attending all the services on Sunday, and, when time permitted, during the week. His friends noticed, about three months before he became actually insane, that he was very dignified and pompous in his manner, he would not take the least notice of his old companions, and for a week at a time had not spoken to one of his own family, with whom he resided. Before meals he would offer up a long prayer, and sign himself with the sign of the cross.

From these cases I venture to make the following remarks:—

1st. That Ritualism appears so entirely to engross the attention of the individual, that there is little or no desire to dwell upon matters beyond the bounds of its own bearing. The train of thought is naturally unaltered, laying the first stone towards disease.

2nd. The length and manner of conducting the services, and the time spent in public and private prayer (occupying in some cases nearly the whole day), combined with the most rigid rules for fasting, can scarcely fail to destroy the strongest constitution, both physically and mentally.

3rd. That it is the younger members of society, their intellects being the most sensitive to impressions, who become its victims.

4th. Where there is an hereditary tendency to insanity, or where mental deficiency exists, the individual is likely to fall a prey.

And, in conclusion, let me ask you whether it is not possible for some steps to be taken to prevent the increasing evil of Ritualism, and to save others from its sad consequences? For in this country, when any contagious disease which is likely to destroy life makes its appearance, hundreds of different opinions are given by an excited multitude, as to the best course to be pursued to prevent its raging further. Now, if such care and caution be taken to keep away the causes of bodily disease, how much more strongly does it devolve upon us to exert every power to check a malady which is more destructive, spreading itself far and wide over our country, taking possession of our houses of religion, ravaging our position in the State, and bringing misery and desolation into our homes? It is

tearing away with it those who should be "as the polished corners of the temple," through its allurements and ceremonial pomp, holding out to its victims a charm as false as it is fatal.

Original Communications.

POISONING BY CYANIDE OF POTASSIUM.

At a meeting of the Swedish Society of Physicians, held April 13th, 1869, Hr. Hallin detailed the following case of poisoning by this salt.

On the 15th March, 1869, in the dissecting-room of the Anatomical Institute of Lund, a medico-legal examination of the body of Ola Ohlsson, a photographer of Tullshö, was made by Nylander, medical candidate, under the direction and supervision of Dr. M. V. Odenius, one of the staff of the Academy. The document accompanying the body represented that O. O., conformably to report, died on the 8th of March after swallowing some cyanide of potassium in solution. From the report of the *post-mortem*, we gather that on external examination of the body nothing worthy of note was to be seen. Internal examination revealed a considerable stagnation of blood in the membranes and substance of the brain. Regarding the cavity of the chest it is remarked: "Upon opening the thorax, the lungs did not collapse; they were partly bound to the chest walls by old bands of adhesive matter; in each pleura there was about half a pint of thin, dark red, transparent fluid. The lungs were everywhere pervious to air, crepitating before the knife; in the upper portions, light red, of ordinary consistence; in the lower parts, darker, reddish grey, somewhat soft; when squeezed, pouring out from the cut surface in the lower portions a dark, viscid, frothy blood, about which, however, it is remarked that its (*i.e.*, the blood's) surface is not clear and bright, but is covered with a lustreless film; in the upper portions of the lung, the fluid, which is pressed out from the cut surface in a tolerably viscid state, is frothy, reddish grey, almost like an emulsion. In this fluid, as well as in the lung-substance generally, appear numerous small, yellowish white, here and there brachy, soft, cylindrical bodies, which on further examination are seen to consist principally of finely divided fat, and they lie in the finest ramifications of the wind-pipes (bronchioli); a like substance is also met with in the lung vesicles; in the somewhat larger bronchia such cylinders are not found, but scattered lumps of a similar nature. The mucous membrane of the trachea and of the bronchi is light red, and covered with mucus; in the trachea a number of dirty, whitish grey, pappy, pap-like masses, resembling curdled milk; in the throat, which is otherwise free, a similar mass is found. The pericardium contains a small quantity of clear fluid, the right side of the heart being full of a dark liquid blood, without coagula. The heart itself tolerably large and covered with fat; the left side of the organ empty, firmly contracted; muscular and valvular structures and openings healthy."

The liver, spleen, and kidneys were much congested. The stomach, which had previously been taken out tied below, of ordinary size, contained about half a pint of whitish grey fluid, of the consistence of pap, in which might be distinguished grains and rather small pea-like lumps; its mucous membrane everywhere uniformly and vividly injected, only in the pylorus tract green, discoloured and softened (*gastromalaktia*). From neither stomach, lungs, heart, nor other organ could any smell of bitter almonds be detected.

Chemical analysis of the blood and of the contents of stomach was carried out in the following way:—"The

blood, alkaline in reaction, was acidulated with acetic acid, and distilled in a water bath. A portion of the distilled liquid, which was perfectly colourless, was mixed with pure liquor potassæ, then with a protosalt of iron, on which a dark precipitate formed, which was dissolved by pure hydrochloric acid, without any deposition of prussian blue, even after a lapse of five days. Another portion of the same distillate was mixed with a few drops of yellow bisulphide of ammonia, warmed until smell and colour had disappeared from it, filtered into a clean porcelain capsule, the precipitated sulphur being thus removed; acidulated with a drop of pure hydrochloric acid, and mixed with a small quantity (less than a minim) of dissolved perchloride of iron; whereupon the liquid immediately assumed a faint, but evident light blood-red tint, which appeared most pronounced just when the perchloride of iron came into contact with the previously clear and colourless fluid, and became after a short time somewhat lighter, until at length the colour was discharged after several days (trace of hydrocyanic acid). With one and the same result also were the contents of the stomach examined."

Further careful analyses for *vegetable poisons* (colchicine, digitaline, picrotoxine, veratria, strychnia, atropia, nicotine, &c.) were instituted, as also for *metallic poisons* (lead, copper, arsenic, mercury, &c.).

The opinion given on oath was to the following effect:—"Of the alterations found on a *post-mortem* examination the appended particularly demand attention, namely, hyperæmia in the brain, heart, and several of the abdominal viscera, the nature of the blood, and also various conditions in the air-passages and lungs. The fact that in the last-named organs, foreign materials were met with of the same nature as those which were found in the throat and stomach, can indeed be explained only on the supposition that they were inspired during life, when they penetrated even into the bronchia and air vesicles. The intrusion of a number of such foreign masses into the lungs can scarcely take place so long as consciousness be maintained, and the sensibility of the larynx be not seriously diminished. It may be assumed that a considerable difficulty of breathing occurring during a more or less unconscious state, caused the strong inspiration, as a consequence of which these were found here and there in the throat, and what are probably vomited matters were drawn into the lungs. As all traces of external violence were wanting, and as no other cause of death was discoverable, also since as well the trade of the deceased, as the traces of poisoning by hydrocyanic acid found on chemical analysis, support the presumption that cyanide of potassium, or some other poisonous preparations containing cyanogen was taken—there is the highest probability that this poison, which is well known to occasion loss of consciousness and dyspnoea, in the present case also produced the same effects. The appearance of hyperæmia in most of the internal organs agrees also with the idea of a dyspnoea arising from the complete stoppage of the air-passages, and of the immediate operation of the poison. Why from the chemical analysis so small a quantity only of hydrocyanic acid could be demonstrated as present, the long time which elapsed between the occurrence of the death and the examination very easily explains.

"On the ground of what thus appeared, partly on *post-mortem* examination, partly from chemical investigations, with the highest degree of probability I consider it to be proved that Ola Ohlsson, photographer, of Tullersbo, died in consequence of swallowing poison (cyanide of potassium)."

The case under review possesses interest on the ground of the unusual *post-mortem* phenomena observed, which has shown that the contents of the stomach may, during respiration, penetrate far down into the bronchioli and lung vesicles; a fact which, as the maker of the autopsy states, may be considered as a consequence of the dyspnoea attended by deep inspirations that are such prominent symptoms in poisoning by cyanide of potassium or other preparations of cyanogen.—*Hygæia*, June, 1869.

CASES IN COUNTRY PRACTICE.

By JAMES HAYES, M.D., L.R.C.S.I.

CASE OF STRANGULATED FEMORAL HERNIA.

MICHAEL CONNOR, æt. fifty-six, was admitted into the Glin Union Infirmary about nine o'clock on the evening of the 4th July, 1868, under my care, with a strangulated femoral hernia in the left inguinal region. The strangulation took place the previous day; never before complained of rupture. I saw the patient soon after his admission, and found a very tense and painful tumour, the size of a small walnut, in the left inguinal region, with stercoraceous vomiting and abdominal pains. The taxis being tried before his admission, without any effect, by the medical officer of the district, I did not consider it advisable to repeat it. At half-past five o'clock on the morning of the 5th, I proceeded to operate, having put the patient under the influence of chloroform. The division of Gimbernat's ligament external to the sac had no effect. I therefore laid open the sac; it contained a small knuckle of intestine, not much congested; the stricture was divided, and the intestine returned. The edges of the wound were brought together by three sutures, and a towel, folded into a pad, and bandage applied. I had the patient removed to bed, and ordered gr. ii. of opium in pill, to be taken immediately.

I visited him two hours after the operation; he complained of very little pain; the vomiting had ceased. I ordered him plenty of ice to suck during the day.

July 6th.—Slept during the night; everything looks favourable; no return of the vomiting; bowels not yet moved.

The bowels did not act until the third morning after the operation, and then with great pain and difficulty. After the bowels had acted, the patient continued to improve rapidly, and left the Hospital on the 21st, much fatter than when he entered. I received good advice and able assistance during the operation from Dr. Hayes, of Shanagolden, and Dr. Hamilton, of Tarbert. The patient continues in excellent health up to the present.

CASE OF PHYMOSIS.

William Hanley, æt. fifty-nine, widower, stonecutter, consulted me last May. He says that, about eight years ago, while working at his trade in the limestone quarry near Foynes, he received a large wound in the glans penis, it having been accidentally caught between two large blocks of stone; the rubbing of the trowsers against the penis caused him much pain, and, to guard against this, he pulled forward the foreskin and kept it so by bandage. When the glans was healed he could not retract the foreskin, it having become firmly united to the subjacent parts. In the course of a few years he found the meatus getting small, difficulty of voiding his urine, and a fetid discharge. Had medical advice; was supplied with a lotion and syringe; did not derive much benefit from this treatment. Two years ago the orifice of the urethra was so much contracted that he could only pass his water in drops, and even that only after dilating the orifice with a fine-pointed nail, which he always carried in his pocket. The pain now was so great that he was obliged to carry in his breeches a small saucepan filled with cold water, which had to be replaced as it got warm, for the purpose of "killing the burning pain." He suffered a great deal last spring from sleepless nights; often had to remain sitting up all night. His case getting worse, the "doctors doing nothing for him," and, to add to his miseries, his employer threatened to dismiss him, he consulted me. I found the meatus urinarius very much contracted, hard, and gristly, with fibres radiating from the centre, a fetid smell, and I had a great difficulty in introducing a silver probe. I told him the nature of the case, and the treatment to be adopted; he most willingly submitted. The prepuce and glans were

so closely united that I could not introduce a fine silver probe. I enlarged the orifice, which cut like cartilage, and then separated the prepuce from the glans partly by dissecting and tearing. I succeeded after great patience and trouble, and then slipped off the prepuce in the usual way. There was not much hæmorrhage. I dressed the penis with a piece of lint steeped in warm water; he complained of no pain after the operation. The glans healed very soon. The organ is now quite healthy, and the water comes in a large stream. He is now working at his trade at the new church, Rathkeale, in perfect health.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

MERCER'S HOSPITAL.

LOCAL SYPHILITIC PARALYSIS.

By Mr. MORGAN, F.R.C.S.I.,

Surgeon to the Hospital, and to the Westmoreland Lock Hospital, Dublin, Professor of Surgical and Descriptive Anatomy, R.C.S.I.

AMONGST the remarkably obscure yet distressing sequela of syphilitic infection, the various and capricious nervous affections and their complications are of great interest and difficulty.

While some nerves, as the *motores oculorum*, are so frequently affected by paralysis of syphilitic origin that its very existence leads to the conclusion of there being such a source, yet others seem very much less subject to this influence; thus, though the cranial nerves seem to be more directly susceptible, the spinal comparatively escape.

Cases of paralysis of some groups of muscles, combined at the same time with a certain amount of neuralgia, have been noted, as escaping suitable treatment, and thus remaining stationary for a long time, till the occurrence of a rash or of some syphilitic manifestation gave the clue to a correct diagnosis. Lancereaux gives three cases of sciatica which had long resisted treatment, but yielded "as if by enchantment," when, a syphilitic cause being suspected, mercury and iodine preparations were administered. Vandekerke gives a case of ilio-scapular neuralgia which was cured by anti-syphilitic treatment.

Niecep has furnished a well-marked case of a "man, aged forty-two, who was treated for rheumatic pains in the back, neck, and arms, and afterwards had atrophy of the upper part of the neck and left arm, with weakness of the muscles in these regions, the atrophy and weakness resisted moxas and blisters, until the occurrence of a syphilitic eruption suggested the administration of iodide of potassium, which agent cured all the symptoms."

The following very typical case came lately under my care, and demonstrates how the syphilitic influence may be cloaked and escape observation.

J. W., a strongly built man, aged about twenty-nine, an engine-driver, was admitted to hospital on the 13th November, 1868. He states, on close examination, that about three years ago he got a sore on the prepuce, followed in some days by bubo, which suppurated and was opened; he had no further symptoms, and married a healthy young woman in one year after. His wife showed no symptoms of being infected, but she produced successively three children—the first was dead-born, and decomposed—the second was born at seven months, and died in nine days—the third lived and is healthy.

He has been for several months past suffering from paralysis of the deltoid and scapular muscles of the right

side, which now show very considerable flattening; he cannot raise his arm, or use the limb, indeed in any way. The muscles are wasted to about one half; he suffers from severe neuralgic pain over the deltoid; in the course of the circumflex nerve and also along the inner side of the arm to the bend of the elbow.

He has had no idea of there being any specific cause, till I was directed to the source by his having alopecia, and copper-coloured spots on the trunk. He had been treated by tonics, blistering, and galvanism locally applied. That the origin of his symptoms was of a syphilitic nature, I had little doubt. I therefore at once administered large doses of the iodide of potassium, gr. xij. four times daily, and instead of exercising the limb, I directed him to keep it at rest, to remain in bed, and use sedative liniment over the deltoid. After the first three days of this treatment the neuralgic pains diminished, and in a fortnight the improvement was most remarkable, so much so, that in four weeks from his admission he was able to leave hospital and resume his occupation. The result in this case was most striking and satisfactory, the neuralgic pains began to yield after the first half-dozen doses of the iodide, and the improvement continued steadily to progress. At first he could not raise the arm at all; in four days he could bring it from the side; and in eight was able to raise it to the head. The iodide of potassium was then combined with iron, and stimulating liniment well applied over the muscles of the shoulder. His health rapidly improved, and he put up flesh.

Another still more marked and urgent case occurred in the person of J. L., a coach-smith, who gave the following history:—About eight or nine years ago he contracted a sore and bubo, which suppurated in a fortnight; he continued free from any symptoms for years, and never had another sore, when he got an eruption of blotches on the skin, which continued for some weeks. He afterwards suffered severe osteoscopic pains, and in March twelvemonth his health got broken down, and he got nodes on the clavicle and tibial periostitis.

He now had very considerable paralysis of both upper extremities, the muscles on both sides being fully a third wasted; he was quite incapable of raising the arms to the head, and even fed himself with difficulty. He had been unable to pursue his business for five months, and was much distressed by neuralgic pains down the arms, and also up the neck. There is a slight tenderness along the dorsal region of the spine, and, as in the former case, the neuralgic pains took the course of the circumflex nerve and along the inner side of the arm.

I treated him with large doses of iodide of potassium, and sedative liniment over the shoulder and back; in four days, as the iodide began to exert its influence, the pains sensibly diminished, and in ten days the improvement was very marked. After five weeks' treatment, the muscular power being evidently restored, he was discharged cured.

This patient came under my care during the past week for an accident. He showed me how completely restored he was: that he never had any return of the paralytic symptoms now for ten months, and has been able to make vigorous use of his arms in his trade as smith.

In neither of these cases was there the slightest evidence of any inflammatory state of the shoulder-joint; there was no tenderness on motion or handling, and no special position of the limb caused pain.

In the first case, the paralytic affection seemed extreme in the one arm on contrasting it with the sound limb; but in the latter, the loss of power was most evident and distressing. The iodide of potassium was pushed from 12 grs. to 25 grs. three times a day; as the symptoms yielded directly, there was no necessity for pressing it further.

It is remarkable that both these cases of constitutional infection dated from a sore and *suppurating bubo*.

At the Westmoreland Hospital I have had a similar case of one shoulder affected, and where no inflammatory symptoms were present. Here, also, the iodide of potassium effected a rapid cure.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE lengthy nature of the proceedings of the Science Congress at Exeter renders it impossible for us to attempt a full report of the whole, although many of our readers would no doubt be interested in the progress of Departments with which they are not necessarily brought into contact. We propose to add to what we have already published some gleanings from the proceedings in the Sections in reference only to those subjects which have the greatest claim on a medical journal.

ON THE PHOSPHORESCENCE OF SEA AND OZONE, IN CONNECTION WITH ATMOSPHERIC CONDITIONS.

Dr. MOFFAT detailed the result of observations taken at sea, to show that ozone is in maximum quantity with decreasing readings of barometer, and the conditions of the south or equatorial circuits of the atmosphere. It is supposed that there might be some connection between ozone and the phosphorescence of the sea.

ON THE OXIDATION OF PHOSPHORUS, AND THE QUANTITY OF PHOSPHORIC ACID EXCRETED BY THE KIDNEYS IN CONNECTION WITH ATMOSPHERIC CONDITIONS.

Dr. MOFFAT stated that from results of observations on the luminosity of phosphorus in connection with atmospheric conditions for a period of six years, it appears that periods of phosphorescence and ozone periods commence, continue, and terminate under the same atmospheric conditions. While the barometer is increasing, and the wind is veering towards the north, phosphorescence diminishes in brilliancy, and ozone increases in quantity, and so on in various quantities, according to the change of wind and barometrical influence. Liquid and gaseous bodies when in contact with phosphorus in a non-luminous state become, under certain conditions, ozonised. As venous blood contains phosphorus, which in coming in contact with the oxygen of the air is converted into phosphoric acid, and combines with certain alkalis and earths in the *liquor sanguinis*, and forms phosphates of soda, magnesia, and lime, it is not unreasonable to suppose that the quantity of phosphorus oxidated and the phosphates formed in the system, and eliminated from it through the kidneys is in some degree determined by the pressure and temperature of the atmosphere, and the state of the weather generally with a view to ascertain the quantity of phosphoric acid excreted by the kidneys. Dr. Moffat tested urine, under certain conditions, viz., that of a healthy man, and by the results it appears that the amount of phosphorus oxidised in the air, and the amount oxidised within us depends upon similar atmospheric conditions.

ON A REMARKABLE STRUCTURAL APPEARANCE IN PHOSPHORUS.

Professor TOMLINSON said that a very remarkable appearance in phosphorus was seen some months ago by Mr. James John Field, F.C.S., who requested the learned Professor to account for it. Mr. Field placed about half-a-dozen sticks of phosphorus in a cylindrical jar containing water, which rose about half an inch above the ends of the sticks, and the jar was closed with a bung. This jar was placed in a cellar, where it remained undisturbed about three years. The cellar is flagged with stone, surrounded by damp walls, and almost entirely protected from light and currents of air. The maximum temperature probably did not exceed 50 deg. or 55 deg. Fahr. After this long repose, the jar was taken into the laboratory, when it was found that the level of the water had sunk to about one-third of its original height, and the liquid left in the jar had become as dense as the strongest syrup. The portions of phosphorus that rose some inches above the liquid, instead of being cylindrical as before, were conical, from a sharp point to the full diameter, and each cone had a double spiral running down from left to right as if two flat tapering bands of the substance had been made to cohere at right angles lengthwise, and then twisted into pointed rods, just as if the sticks had been mounted in a screw-cutting lathe geared to cut a coarse tapering double spiral. The sticks had also changed from the creamy opaque surface to a translucent appearance, from the surface of the liquid up to the points. The learned Professor then explained the appearances above described. First, the wasting away of the sticks and

their conical form are clearly effects of slow combustion, diminishing in intensity downwards. The continued combustion diminishing the evaporation of the water must have been due to a badly-fitting cork, which, during a falling barometer, allowed a portion of the moist air to escape from the jar, and, during a rising barometer, allowed a portion of comparatively dry air to stream in. After giving the most conclusive reasons for the spiral markings, he concluded by stating that when the particles approach the orifice they converge to a point beyond it; and as this point in the phosphorus to which the relating lines converge, though fixed in or near the tube, is being constantly shifted in the phosphorus, by being drawn out and moulded in the tube; the converging lines also are drawn out, and thus give the appearance of a double spiral. Professor Calvert, Dr. Nevins, Mr. Braby, Mr. Wm. Huggon, and Professor Tomlinson took part in the discussion in this section.

REPORT OF THE COMMITTEE ON THE CHEMICAL NATURE OF CAST IRON.

The committee consists of Messrs. F. A. Abel, D. Forbes, and A. Matthiessen. The committee reported that they entrusted the preparation of pure iron to Mr. Matthiessen, who carried out this part of the investigation in conjunction with M. Szizepanowski very satisfactorily. These gentlemen expressed a hope that next year a great deal of very useful information will be obtained on the chemical nature and physical properties of pure iron and its alloys. According to an analysis made by Professor Abel, the iron contained in a hundred parts only 0.00025 parts of sulphur. To another analysis the amount of sulphur found by M. Prus. Szizepanowski was 0.0007 per cent. The amount of substance taken for each analysis was about 30 grammes. Phosphorus and silicon were carefully tested by both the above analysts, and found to be entirely absent. Prof. Matthiessen then detailed very elaborately the nature and properties of pure iron, and the best and most approved methods of fusion and filtration.

ELECTROLYTIC IRON.

Dr. JACOBI read a paper on the electro deposit of iron. The learned Professor illustrated his remarks by a series of plates of extreme beauty. The solution from which the metallic iron was deposited consisted of a double salt, the sulphate of iron, and magnesia. It was found desirable to coat the recipient of the deposit with a thin film of nickel or copper. Specimens illustrating the application of the electro deposit of iron to purposes of engraving (aided by photography) were also exhibited.

RUST OF IRON.

Professor CALVERT gave some interesting results of his experiments into the nature and condition of rust. Oxidation of the bottom of iron ships he thinks may be prevented by an external coating of a preparation of an alloy of lead and antimony, while an alkali is placed in the bilge water within the vessel.

THE CHEMISTRY OF FLINT INSTRUMENTS FOUND IN THE DRIFT. BY W. D. MICHELL.

A very long paper, discussed from a purely chemical and mineralogical standpoint. The evidence for the natural formation of these implements in opposition to their art formation, was derived from various writers on this subject, and from careful observation, as also from a chemical and mineralogical investigation into the nature of flints and their allies—obsidians, chalcedonies, and quartzites. The paper described the remarkable forms of flints found in raised beaches and river-bed gravels, their chemical changes, and the mechanical methods in which they beach up and flake in the beds, &c., even on the surface, as well as the atmospheric changes upon them in the way of disintegration. The conclusion arrived at was that these chipped flints of the Drift Beds, &c., styled Flint Implements of the First Stone Age, are nothing more than lithological curiosities. Several gentlemen took part in an animated discussion.

SEWAGE.

A CHEMICAL METHOD OF TREATING THE EXCRETA OF TOWNS. BY E. C. C. STANFORD.

This paper, and the one succeeding it, attracted a considerable amount of local attention, and was intended to show that the present system of dealing with the excreta of towns

was entirely a failure. The use of lead pipes was most prejudicial; the evaporation of deleterious gases and the immense damage to rivers and streams call for some other means of dealing with the important question. The dry closet system is the great remedy; but, inasmuch as the use of *earth-closets* was beset with difficulties, the adoption of charcoal as a deodorant was an effectual and economical remedy. The objections to the use of the water system were—1, cost of works; 2, cost of closets; 3, large amount of water required; 4, pollution in discharge; 5, its value as manure reduced by dilution; 6, generation of noxious gases. In addition to this, there is the excess of mortality, tainting the atmosphere, and the evils of drinking impure water. The objections to the dry system are—1st, the large quantity of earth required; 2nd, the difficulty of obtaining the quantity required, and of drying it. Now, these difficulties are disposed of by using charcoal. Sea-weed charcoal, when procurable, is the best absorbent and the cheapest. This deodorant can be stored for any length of time, and re-burnt if necessary, yielding valuable products.—Mr. Hope thought that it was not so much an engineer's question as a chemist's; and he would desire to have a Committee of Chemists, under the auspices of the Association, with a necessary grant of money, to test the question effectually.—Mr. Alderman Rumney, Manchester, gave some details of the sewage plans adopted in that city, and was followed by Mr. Webster, who thought the dry system could entirely meet the difficulty, but local circumstances were sometimes in the way of carrying out even that which appeared to be the most effectual.—Dr. Paul thought there should be no antagonism; but that the engineer and chemist should work in harmony in order to solve this most important question. In an economical point of view, the agriculturalist would look at it at its value for manure, while the towns would be only anxious to get rid of their refuse.—Mr. Phillips, of Exeter, referred to the two plans which had been set before the Section this day, as the wet system and the dry system; he had paid much attention to the subject, and came to the conclusion that the dry system must be adopted—if not immediately in our large centres of population, at least in our more sparse neighbourhoods.

UTILISATION OF TOWN SEWAGE.

Mr. THOMAS D. BARRY read a long paper on "The Utilisation of Town Sewage." After expressing an opinion adverse to the application of Mr. Moule's dry system to large towns, he proceeded to criticise the irrigation system, especially as developed at Edinburgh, Worthing, and Croydon, and contended that fields subjected to constant irrigation, can produce nothing but rank coarse grass, and that if any other crop is to be grown in those fields, the flow of sewage must be discontinued. Indeed, unless this was occasionally done, he did not think irrigation would benefit land. The effects of irrigation were most beneficial on clay and sandy soils, and really good land did not give evidence of so much improvement. He could see but little difference between the effects of sewage irrigation and the pure water irrigation in Lombardy and Piedmont. The advocates of irrigation claimed that their system possessed two advantages, viz., freedom from offensive smell, nuisance, or injurious influence on the health of a district, and a remunerative return for money laid out. He proceeded to dispute both these propositions. With respect to the latter, he argued that the apparent success was due to accidental circumstances, and had no permanent reality, and brought forward several illustrations in support of his views. He also argued that the system was not so free from nuisance, &c., as was claimed for it, and quoted authorities on the matter, and then proceeded to contend that the land was deteriorated by repeated and successive applications of liquid sewage. He expressed his adherence to the system of filtration, as more suited to certain localities and large towns. He explained that at Leamington the town ashes, road scrapings, &c., were mixed with the sewage, and a dry manure formed, which found a ready sale among the farmers, produced good crops of all kinds of vegetables, and was prepared without any offensive or unhealthy odour.—Dr. Paul said the works at Leamington were satisfactory, as far as the eye went, but it was illusory. Only about one-fourth of the manure was taken from the water, though it seemed perfectly clear. Four per cent. of ammonia was the only component in the manure produced at Leamington which was of any value, and at places where much manure was produced it was sold at from 6d. to 2s. per ton. With regard to the question of profit and

loss, he held that the towns must be expected to pay for getting rid of their refuse, and the real profit was the improvement of the land. He did not see the greater danger to health of spreading the sewage on the land than of pouring it into the water we drink.—Mr. Rumney said it had been stated that either irrigation or filtration must be adopted. This he denied, and explained a plan which is being adopted under the Artizans' Dwelling-house Act at Manchester, which he thought preferable to either.—Mr. Hope, V.C. (of the Barking Sewage Farm), joined issue with Mr. Barry, and defended the judicious use of liquid sewage, and said that where it had parted it was due to mismanagement.—Mr. Stanford compared a company looking for profit from the deposit of sewage to a ferret watching one hole of a rabbit burrow while the rabbit ran out of the other. Irrigation was not adapted to all towns, and he thought it better to make sewage solid by mixing it with something else, and carrying it away, as in Manchester.—Admiral Belcher said that in China and Malay the excreta is allowed to be in proximity to the houses, but no malaria resulted; but if water was allowed to flow over it, fermentation would ensue, and bush fever would follow. The drainage system which we have adopted robbed the land of the fertilizing salts, and conveyed them to the rivers. He was the originator of the Thames Sewage scheme, and he had suggested that the outlet should be extended through Essex, and be delivered by the River Crouch into the German Ocean.—Mr. Barry said he was afraid the dry system mentioned as in operation at Manchester would not answer, because of the difficulty of administration, and the annoyance and danger of carrying the excreta through the houses.

ON THE WATER SUPPLIES TO PLYMOUTH, DEVONPORT, AND EXETER. BY H. BAMBER.

The water used for the supply of Plymouth is taken from the river Meavy, coming down from Dartmoor in an open leat for about twelve miles, and thence carried on in mains of 24 in. and 12 in. in diameter; the total contents of solid matters, after analysis in imperial gallon, being 2.95 at the commencement of the leat above Meavy; and in Plymouth, at a stand pipe, contained 3.25 solid matter. This, although a good water for manufacturing purposes, acts rapidly on iron pipes, but this is counteracted by coating all new pipes internally with asphalt. The Devonport supply is derived from near the source of the Dart, and is conveyed by an open leat of more than thirty-four miles to the town. The analysis gives at an early stage 4.05 solid matter. Its organic constituents, like those of Plymouth, were principally chloride of sodium and sulphate of lime. A dark infusion in the water is probably due to peaty matter. The water used for Exeter is taken from the Exe at Upton Pynes, where it is pumped into the reservoirs at Danes Castle, behind the gaol. After filtration it is distributed through the city. When the water is clear, as at present, the supply is pumped directly from Pynes to certain parts of Exeter and Heavitree which are at a high level, but when the water is foul, it is all sent to the filtering reservoirs, and thence to its destination. A sample of water was taken from a tap in the house of the Mayor, H. S. Ellis, Esq., as it was running into the cistern. There was a red sediment in the bottom of the tank, and on pressing the ball-cock to increase the supply, it came out at first quite red, from containing in suspension the rust of iron. After this it seemed to bring with it from the pipes, in suspension, a brown substance, which soon settled. At last a clear sample was obtained. The analysis was found to contain in the imperial gallon:—

	Grains.
Inorganic matter	11.43
Organic and other volatile matter	0.16
Total solid matter	11.64

The inorganic constituents consisted of carbonate and sulphate of lime, carbonate of magnesia, chloride of sodium, and a trace of nitrates. It contained 2.15 grains of chloride of sodium per gallon, and .005 grains of ammonia. Its hardness before boiling was 7.60, after 2.27. This is a good water, is moderately soft, and becomes very much softer on boiling; it is supplied by the Water Company, and should be always filtered, if possible. The supply from St. Thomas is taken chiefly from a well in the gravel, and supplemented by the Exeter Company. By means of the black board an elaborate analysis was shown, from various points and under various circumstances.—Dr.

Shapter did not think the analysis of the Exeter water by the reader of the paper at all trustworthy, and would read the analysis by Mr. Hill, analytical chemist:—

	Nov. 27, 1867.	Aug. 3, 1868.
	Grains p. gal.	Grains p. gal.
Volatile and combustible matters	1.40	1.40
Chloride of sodium	2.40	2.04
Sulphates of lime and magnesia	5.09	6.49
Carbonates	none	1.13
Nitric acid	none	none
Total solid matter	8.89	11.06
Hardness (27th November, 1867)—before boiling	4.7	4.7
“ “ “ “ “ after	“	“
“ (3rd August, 1868) “ before	7.5	6.5
“ “ “ “ “ after	“	“

Mr. Norrington thought Dr. Shapter was in error, and that Mr. Bamber's analysis was most in accordance with the experience of the inhabitants.—Mr. Beardman and Mr. Thorp, of the Rivers Commission, also entered into the discussion.

THE HYDRAULIC SCRAPING OF THE TORQUAY WATER MAIN.

Mr. R. E. FROUDE read a paper on the operations which were rendered necessary by the continually decreasing supply of water, which resulted in raising the supply from 320 gallons in 1864, to 564 gallons per minute in 1867, to 634 gallons in 1868, and to 660 gallons in 1869. The plan adopted was that of passing through the main a piston, armed with a scraper.—Mr. W. FROUDE read a very abstruse paper on some difficulties in the received views of fluid friction, which elicited some discussion, and was warmly received.

THE METHYL SERIES.

Dr. RICHARDSON read his "Report on the Physiological Action of the Methyl Series," which stated that the use of some of these agents had greatly increased during the last twelve months, especially in France; the bichloride had been very safely used, having been administered 2,500 times without any fatal result. With ordinary skill and ability on the part of the operator, insensibility could be produced with about six minims, and in forty seconds of time, which was long enough for all simple operations, and the patient recovered in from three to five minutes. Dr. Richardson alluded to the new substance chloral, discovered by Liebig, the physiological effects of which were about the same as those in the methyl series, but he had not yet examined it himself. The investigation of the alcohols was most elaborately described, and as an anaesthesia the use of alcohol was condemned as being too slow and too prolonged. He could not place the alcohols in any other position than other chemical bodies—they were certainly not foods, nor could they either give strength or supply material for strengthening the tissues, or throw force into the tissue, which had been supplied by other matter. It was time that the learned in the profession should recognise the true position of these agents, for seeking force in alcohol was like seeking for sunlight in a subterranean cavern. The report referred to the means of restoring suspended respiration, during which Dr. Richardson exhibited the bellows which he had constructed to aid in restoring respiration artificially. He had, by the aid of the apparatus, restored respiration from two to four minutes after all appearance of it had ceased in dealing with rabbits and other animals, but he could not always succeed, and why he did not he was totally unable to say. A brief discussion followed the report, and in reply, Dr. Richardson, speaking of the means used to restore respiration, said that the operator should always have the power to raise the temperature of the room in which he worked, and, as this remark applied to the recovery of the apparently drowned, all receiving houses should contain a room in which the temperature could be raised to 140 or even to 160 degrees, at the will of the operator. There was always in the case of suspended respiration a lowering of the temperature, and the air used in producing artificial respiration should be warmed artificially before being passed into the lungs.

RESPONSIBILITY OF HABITUAL CRIMINALS.

Dr. WILSON read a rather phrenological paper entitled "On the Moral Imbecility of Habitual Criminals, exemplified by Cranial Measurements." Dr. Wilson's theory was that habi-

tual criminals did not possess such an amount of intellect as to enable them to discriminate between right and wrong, and that the majority of them were devoid of moral sense. The habitual criminal was of a low type of intellectual development, and some of them were so backward as to be unable to surmount the rudimentary difficulties of education. The measurements submitted by Dr. Wilson were from 464 separate measurements, and all showed a cranial deficiency, especially in the anterior lobes of the cerebral portions of the brain. Dr. Wilson recommended the adoption of a system of treatment of criminals similar to that in practice in Ireland—a system of punishment more reformatory than punitive. He also suggested that means should be taken to test a criminal, after he had been confined for a certain period, and that if he did not withstand the test he should be for his own sake and also for the sake of society kept in confinement. This paper excited a good deal of opposition.

VITAL STATISTICS.

Dr. JAMES STARK, Registrar-General of Scotland, produced a mass of statistics of Scotland comparing the mortality in towns with that of the rural districts, and drawing this general conclusion that, though the mortality in towns is much greater than that in the rural districts (especially among young people under fifteen years), the principal contagious diseases carried off as great a proportion in the country as in the towns, and the increased mortality in towns was owing to general depreciation of health and not to the zymotic and respiratory diseases.—Dr. Shapter stated that some eight years ago he compiled the statistics of Exeter as compared with those of Devon on the same plan and with the same objects as those of Mr. Stark, and he arrived at precisely the same results.

VACCINATION.

Dr. HENRY BLANC, F.R.G.S., Staff Assistant Surgeon, Bengal Army, read a paper on "Human Vaccine Lymph and Heifer Lymph Compared." Dr. Blanc stated that compulsion is always distasteful, but that, if the Vaccination Act, 1867, were wisely and properly applied, it would soon lose much of its compulsory character, and vaccination, instead of being avoided and dreaded by a large section of the public, would be hailed by one and all as one of the greatest blessings human mind had bestowed on mortal man. As the matter stands, however, Dr. Blanc fears that, if no steps be taken to render vaccination more perfect, the resistance on the part of the public will become so general that the law will become a dead letter. The declared adversaries of vaccination were not half so dangerous to the safety of the system as are those who persist, in spite of repeated warnings, in declaring that no risk of the transmission of disease exists. The anti-vaccinators, however, had, by their persistently exaggerated statements, done good service by calling the public attention to a subject of such great importance. In commending the Vaccination Act, Dr. Blanc makes an essential condition, that the lymph forced upon the public shall be perfectly pure. The vaccine lymph at present used, he unhesitatingly declared, did not answer this description. In treating the subject, he dealt with two questions: 1st, Can disease be transmitted with humanised lymph? 2nd, Is humanised lymph of long standing a prophylactic against small-pox? In answer to the first question, he did not believe that every possible disease could be transmitted by lymph. To suppose that human cholera and some other forms of disease were produced by vaccination was not only irrational, but simply absurd; but at the same time he was compelled to admit that the transmission of disease was not only possible, but must be received as an acknowledged fact. Dr. Blanc gave instances to show that two forms of disease, particularly a kind of skin disease and syphilis, had been unmistakably transmitted by vaccination. With regard to the latter, Dr. Depaul, director of public vaccination in France, in a discussion at the French Academy of Medicine, had brought forward many instances, drawn from the observation of cases of children of soldiers who had been vaccinated at military hospitals, and the cases showed that nothing but a most rigid and searching examination could enable a medical man to judge whether syphilitic taint existed or not. With regard to the second question, as to the efficacy of humanised lymph, Dr. Blanc answered it in the negative, as he found the humanised lymph of long standing lost much of its anti-variolic power, and stated that, far from being alone in this opinion, he was supported by all the best authorities on vaccination. M. Simon, after a careful study of the pro-

gressive successes of vaccination in the Prussian army, found that the vaccinations of 1836, when tested by subsequent susceptibility to cow-pox, were not so successful as those of 1813. There was no longer the same immunity as was formerly given, and the cases of fatal result from vaccination had also largely increased. Dr. Blanc quoted copiously from returns of various public institutions to show that the increase of cases of post-vaccinal small-pox had steadily increased since the use of humanised lymph became general. During the small-pox epidemic at Norwich only 2·10 per cent. of those cases which were observed by Mr. Cross had been vaccinated. Mr. Marson, of the London Small-Pox Hospital, in the course of 30 years' experience, stated that cases of small-pox occurring after vaccination had steadily increased since 1836. From 1835 to 1845 the admissions of small-pox after vaccination to the London Small-Pox Hospital, were 44 per cent.; from 1845 to 1855, they were 64 per cent.; and from 1855 to 1865, 78 per cent.; while, during the years 1863 and 1864 they were 83 and 84 respectively. On the other hand, on examination of the cases of people who had taken cow-pox from milking cows, it was found that they still enjoyed perfect immunity from small-pox, as was shown by Dr. Blanc in a variety of statistical extracts. The remedy he proposed was simply to return to the system of Jenner. Vaccination direct from the heifer or animal was no new or untried system, and had been established in many large cities of Europe. The advantages of the system were a removal of the danger of infection from other disease, as the bovine race was not subject to such diseases as might be transmitted to man; that the spontaneous cow-pox was not likely to lose its essential qualities; and it was easy always to have on hand a good supply of vaccine matter by these means. No fatal results had been recorded as arising from the use of the animal lymph, and the conclusion of Dr. Blanc is thus to render compulsory vaccination efficacious, and to complete the great work of Jenner they must return to the system of taking the lymph from the animal, and so restore the glory and usefulness and prestige of Jenner's great remedy.

MEAT-BROTH.

Kemmerich makes the following assertions:

1st. A small dose of concentrated meat-broth increases the force and frequency of the heart's action; large doses act toxically, and produce death, with symptoms of cardiac paralysis.

2nd. The active principle upon which the above effects depend, consist mainly of the potassa compounds contained in meat-broth.

3rd. The salts of potassa, small and medium doses, do not retard the heart's action, but on the contrary stimulates it.—(*Pflüger's Archiv f. d. ges. Physiologie*, 1868.)

As the first rather startling assertion has a very important practical bearing, it would be well for others to follow up the investigation.

We hope that patients have not been unwittingly killed with beef-essence in days gone by!

NUX VOMICA IN CHRONIC DYSENTERY.

In a recent number of the *Bulletin Gen. de Thérapeutique* is an article by Dr. De Savignac, upon the use of nux vomica in dysentery and dysenteric paralysis. His theory is, that the cause of the disease lies in an affection of the spinal cord, which causes paralysis of the motor nerves of the large intestines, and of the vaso-motor nerves which supply its blood-vessels. If this be correct, nux vomica would appear to meet the indication precisely. Dr. Savignac, who has had large opportunities for observation in the marine hospitals of Toulon, claims excellent results.—*N. Y. Medical Gazette*.

ON THE FORMATION OF FUNGOID GROWTHS IN MILK.

Hessling, in *Virchow's Archives für Pathologischen Anatomie* states that, if a fine layer of milk is examined just before it becomes sour, amidst the milk and fatty globules there will be found germinal masses of vibriones, such as are seen in substances in the course of putrefaction, and closely resembling the *ascophore*. These growths are not confined to milk, but are found in butter, both fresh and salt, and in cheese. The subject is of importance, as it has led both Hessling and Falger to consider these fungi as a source of intestinal disease in infants brought up by hand.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, SEPTEMBER 8, 1869.

THE PERILS OF POLICY HOLDERS.

It is impossible to take up a subject which, in the face of the collapse of the Albert Office, has a more vital interest to a large number of our professional brethren than that of life assurance. Poor as many of us are—dependant on an uncertain income, which illness or death may at any moment sweep from us—we have found life assurance the only available mode of securing our widows and children from absolute want after disease or early death has deprived them of our support. How terrible, then, is the revelation that our provident savings may have been all in vain: that what we pinched for years to secure has been engulfed in the speculation, or only helped to keep afloat an insolvent concern, and so entice others to a similar fate. No wonder that an indignant loser should utter his sentiments in unparliamentary language, and call the rotten concern a “d—d swindle.” Year after year the Albert went on, taking new premiums, absorbing other offices, and dividing so-called profits. It spread its net far and wide, and great was the take. The policy holders have all been deluded; the shareholders have lost their money. No one has gained anything except the officials and amalgamators. Verily, it is a swindle; and we sincerely trust that no compromise will be accepted, but that every effort that lawyers can suggest will be made to bring the guilty persons to book; for guilt there must be, when millions that had been consecrated to widows and orphans have disappeared. Who were the guardians of those millions, and what has become of them? It is impossible to pretend that they have been lost by fair trade. Life assurance as a business is perfectly safe: at any moment it is possible to arrive at an exact estimate of the state of affairs; and consequently those behind the scenes might have known, and ought to have known, the true position of the Albert.

Since the announcement of the failure of the Alber

carried ruin and desolation into thousands of households, there have been many proposals for preventing such another catastrophe. One of the most important for those already assured in any office is the publication of full and particular accounts. We would counsel every policy holder to ask for such accounts. If the movement should be general, no office dare refuse. To deny information would be to excite suspicion, and sound lives would feel it better to make terms with a new office, rather than continue in one in which they had lost confidence. Combination to a slight extent would enable them to do this. Another point is, whether any offices should be proprietary. For shareholders, as compared with policy-holders, we have no room for pity. If they put themselves at the mercy of directors or managers, they only lose the money they have invested in the hope of profit; but the poor policy-holder loses far more, oftentimes the savings of a lifetime, the hope of declining years, the provision made for wife and family. For our part, we fancy mutual offices less complex, more public, and less liable to such proceedings as have brought the Albert to ruin.

Now, we may consider further how far the law should regulate assurance. Some would like to see the Government conduct the life assurance of the country. Already Government does insure lives to small amounts, for the benefit of working men; and it may be questioned whether the limit put to Government might not advantageously be extended. At the same time it is to be remembered that it is quite contrary to the genius of British institutions to foster a dependance on the State, or to encourage the paternal solicitude of Government.

America has always controlled, more or less, the business of life assurance, and the plan has worked so well that the advocates of State interference will not fail to urge upon us a similar supervision. Some information on this point will, no doubt, be welcomed, and we therefore add some of the regulations that exist in New York.

A superintendent of the insurance department, who holds office for three years only, and must give a bond for 10,000 dollars, with two sureties for the faithful discharge of his duties, and is forbidden to have any kind of interest in or connection with insurance companies, is appointed by the State. The expenses are defrayed by fees and fines, any deficiency being made up by a tax levied on assurance companies. Life insurance companies are not permitted to undertake fire or marine insurance, &c. The different companies are all subject to the same laws and regulations. Separate companies, separate capitals, and separate accounts are required for each kind of business, and the first division is limited entirely to insuring lives and granting annuities.

No company is allowed to commence business with a less capital than 100,000 dollars, paid up and deposited in approved securities with the insurance department, and not less than thirteen may form themselves into a company. These regulations complied with, a certificate is granted by the superintendent, which is to be authority for commencing work. On taking any risk, whether in annuity or life insurance, it is compulsory to set apart at once a sum which, annually invested at a low rate of interest in Government securities, will be sufficient to discharge the policy at maturity.

The superior officers of the company, with the secretary, actuary, or a majority of the trustees, must prepare on oath, and deposit in the insurance department on the 1st

of January in each year, or within sixty days afterwards, a statement setting forth in a clear form the number of policies issued or annuities granted during the year; the amount of assurance effected thereby; the amount of cash taken in premiums; the amount of cash in interest and all other receipts; the different items to be specified; the amount in losses paid during the year; the amount in losses unpaid; the amount in management expenses; whole number of policies in force; amount of consequent liabilities and all other risks; amount of capital stock; amount of accumulation, stating whether received in purchase of annuities, or, if otherwise, how? amount of assets, and how invested, whether in real estate, bonds, mortgage, Government stock, &c.; amount of dividend unpaid; a tabular statement of policies at present in force, whether for the whole term of life, or any shorter term, showing how many for each term, and for what amount of liability.

The State superintendent supplies the forms for accounts; he can vary the standard of interest assumed. Once in every five years he makes a valuation of all outstanding policies of every insurance company. If he suspect the accuracy of the accounts or the soundness of the office, he can suspend its business, order a special investigation, examine the officials on oath, and publish the result; which not being satisfactory, he can cancel the certificate, and with the concurrence of the Supreme Court the company is compelled to discontinue business, and the effects, including the securities, are confiscated in compensation of the claims of the policy-holders. The expenses thus incurred at the cost of the offending company. Fines are inflicted for violation of the minor provisions of the statute, the lowest being 500 dollars; half of the fines goes to the informer.

Notes on Current Topics.

The Epidemic Diathesis in America.

THE tendency to epidemic disease is decidedly less than last year, not only on the Pacific Coast but on the entire continent. Small-pox has almost disappeared from west of the Sierras, though it clings to some favourite localities elsewhere. Scarletina and diphtheria are endemic in a few places within the borders of the Pacific States. Yellow fever and cholera exist in tropical latitudes, particularly in the disturbed island of Cuba, and threaten from time to time to invade the Atlantic cities. Thus far the year 1869 has been healthy compared with last year. But the usual period of maximum disturbance has not yet arrived.

Modern Homœopathy.

THE *Medical and Surgical Reporter* (Phila.) furnishes the following extract from the proceedings of the Cleveland Homœopathic Medical Society, recently held in that city:

"Dr. S. R. Beckwith asked if the members had any experience to report on the use of bromide of potassium in epilepsy said it was a pretty sure remedy, given in *sensible* doses. He related several cases favourably affected by its use.

"Dr. P. Wilson reported, that late clinical reports had shown that in bad cases of epilepsy, it was safe to give as high as *sixty grains of bromide of potassium three times daily*; that such doses caused temporary insanity, which might be

continued many weeks, and yet disappear on ceasing the use of the medicine."

The same Journal says, that the returns of the London Homœopathic hospitals show a decided partiality for similar "massive" doses.

The late G. W. Mackmurdo, F.R.S.

A LONG and useful career of one of the most amiable surgeons has closed with the life of Mr. Mackmurdo, formerly surgeon to Newgate, to the Ophthalmic Hospital at Moorfields, and to St. Thomas's Hospital. He entered the Council of the Royal College of Surgeons of England in 1850, and was re-elected in 1861. At the last election, on account of his failing health, he declined to come forward again, and thus made way for younger men. He refused the Examinership when his turn came for it. He was throughout life connected with many city institutions, and possessed very large influence in city circles. He seems to have been not only respected but beloved by almost all with whom he was brought in intimate connection.

St. Bartholomew's Hospital.

WHAT is the matter at this old Royal City Hospital? There is to be no Introductory lecture. Surely that is not on account of the discontent that prevails. In the out-patient department there has been much cause for remonstrance, but we had hoped all disagreeables had passed away. We now learn that one of the resident physicians has been suspended for the part he took as to the out-patient's department. The suspension of a temporary officer who feels bound to speak up in the interest of the patients, and of those who will soon succeed him is not a very likely way to promote the interests of the school, or to convince those who contemplate entering, that they are sure to meet with considerate treatment. This matter concerns the staff, and the lecturers and young members of the Profession may fairly look to them to see justice done. We presume resident medical officers would willingly be left in the hands of the permanent staff, and the latter should have influence enough to force their opinions on the lay governing body. We hope some steps will be taken to bring about harmonious action in the working of this great hospital.

Queen's College, Birmingham.

WE have seen a copy of a letter to the patrons and friends of this college, which appears to us to contain points of great importance to its welfare. The letter is signed "A Governor," and, besides enforcing the recommendations of the Charity Commissioners, urges upon the managers in temperate but firm language the necessity of certain substantial reforms. We learn from the letter that the founder of the college is no longer on the Council, and when we call to mind the unwearied work of Mr. Sands Cox, we are as surprised at this as we are proud of that great surgeon's life and example. There must be something strange in a condition which leaves "out in the cold" the one whose indomitable energy and long perseverance created the college of the Midland District. We sincerely trust that for the credit of the Medical School and for the good of the Queen's College, the discussion opened by "A Governor" may lead to some satisfactory arrangement.

Devon and Exeter Hospital.

LAST week the new chapel of this hospital, erected at the expense of Mr. Arthur Kempe, one of the surgeons, was consecrated for Divine service. It is adapted for 150 inmates, and has cost the benevolent member of the unpaid staff some £2,000.

Budleigh Salterton.

MANY months ago, we directed attention to this pretty spot on the Devonshire coast, as a most eligible one for a health resort. It appears from a local paper that Dr. Farr, staying there after the Exeter Congress has come to the same conclusion, and pointed out how the one defect of Salterton—occasional deficiency of water—may be easily removed. The inhabitant would do well to take steps in the matter, as there is no reason why this pleasant town should not become one of the most favoured resorts of our southern coast.

DR. P. ALLEN has been elected aurist to St. Mary's Hospital.

DR. WILTSHIRE has been sent to Dewsbury, Yorkshire, to report on an outbreak of small-pox.

THE Naval Medical Director-General lately inspected the Yarmouth Royal Naval Hospital.

SCARLATINA is on the increase in London. The deaths from this disease in the last six weeks have risen from 75 to 143.

TWO free scholarships at Charing-cross Hospital have been placed at the disposal of the Royal Medical Benevolent College.

A conviction has taken place under the new Pharmacy Act, for selling poison to a person unknown and without a label.

DR. JOHN OGLE has placed in the Museum of St. George's Hospital, a finger found among the glaciers, supposed to be the remains of a guide lost forty years ago.

THE Magistrate was appealed to last week on account of Highgate Cemetery Company objecting to an inscription on a tombstone, to the effect that deceased died of vaccination.

MR. W. H. PERKIN, F.R.S., the discoverer of the aniline dyes, has been appointed to the chair of Technical Chemistry in Anderson's University, Glasgow, founded by Mr. James Young.

IT would seem, from a statement of the patients, who must be the best judges, that a recent report as to insufficient diet at the Surrey County Hospital was quite unfounded.

MR. GLADSTONE will shortly visit Whitby. His health is much improved, but he is still feeble, and has declined

a public reception proposed to be given him by the working men. The kind people of Yorkshire will understand that the right hon. gentleman needs repose.

THE amiable president of the Royal College of Physicians is knighted. We congratulate Sir James Alderson, who is well worthy of the honour, and should be glad to see other eminent members of the Profession receive royal recognition.

MR. L. S. LITTLE has resigned the Assistant Surgeoncy at the London Hospital. Our readers will remember his valuable cases of injection into the veins in the cholera epidemic. He had also successfully performed most of the great operations during his ten year of office.

MR. CURLING, F.R.S., retires from active duty at the London Hospital, after twenty years' service as full surgeon, preceded by fifteen years as assistant. Mr. Curling is still in the full enjoyment of his physical and mental powers, and will now devote himself entirely to his extensive private practice as consulting and operating surgeon. May he long live to enjoy the honour and esteem he has earned by his scientific career.

SCOTLAND.

ADDRESS TO MR. SYME.

To James Syme, Esq., D.C.L. Oxon., M.D. Dublin, F.R.C.S., F.R.C.S.Ed., F.R.C.S.I., F.R.S.E., Surgeon in Ordinary to the Queen in Scotland, &c., &c.

DEAR SIR,—At the thirty-third annual meeting of the Border Medical Association, we, the undersigned members present, unanimously resolved to ask you to receive from us a short address on the occasion of your resignation of the Professorship of Clinical Surgery in the University of Edinburgh.

We desire to convey to you our warmest thanks for the very kind manner in which you have at all times discharged your duties towards our patients and ourselves. We beg also to thank you sincerely for innumerable acts of personal kindness and attention, for which we shall ever feel grateful. Although the members of our Profession generally have resolved to offer you some testimonial in recognition of your inestimable services, and although you have already received a most hearty expression of sympathy and regard from the Profession practising in far distant lands, we trust that it will not be otherwise than agreeable to you to know that the medical and surgical practitioners in your own Border land are equally sensible of, and grateful for, the great advantages they have derived from your precepts and example.

It was with unmingled feelings of sorrow and regret that we heard of your illness; and we now most heartily rejoice to know that you have so far recovered as to be able to resume those professional duties which we have all learned to value so highly. We desire to express the earnest hope that you may yet be long spared to give us the benefit of that eminent wisdom, vast knowledge, and matchless diagnostic tact and skill which have rendered your name famous wherever the science and art of surgery are known. It is to us a source of pleasure that, on the very day of our assembling here, it has become known that you are to be succeeded in your chair by your son-in-law, Mr. Lister, believing as we do that his appointment will be peculiarly gratifying to yourself, in the highest degree acceptable to the Profession at home and abroad, and highly calculated

to maintain the celebrity of the Edinburgh surgical school, in which you have so long been the distinguished master.

With every sentiment of gratitude, respect, and esteem,

We remain, yours faithfully,

JOHN ROBERTSON, M.D., Chairman.
H. S. ANDERSON, M.D., F.R.C.S.E.
GEORGE GILLIES, L.R.C.S.E.
JAS. FALLA, Surgeon, L.R.C.S.E.
ROBERT PURVES (Croupier), Surgeon, Edinburgh.
J. PAXTON, L.R.C.P. & L.R.C.S.Ed.
W. M. MACKENZIE, M.D. Edin., Kelso.
CHARLES STUART, M.D. Edin., L.R.C.S.E.
M. J. TURNBULL, M.D. Edin., L.R.C.S.E., Convener.
HENRY VOST, L.R.C.S.E.
ALEXANDER BROWN, L.R.C.P. & S. Ed.
JOHN HUME, L.R.C.S.E.
DAVID HOPE SOMERVILLE, M.D. Ed., L.R.C.S.E.
WILLIAM BLAIR, M.D. Glas.
JOHN ANGUS M'DOUGALL, M.D.
PATRICK KYNOCK, Physician.
JAS. PITCAIRN BOOKLESS, L.R.C.P. & S. Ed.
HENRY R. FAUCUS, M.D.
WM. ALBERT PAXTON, M.B. T.C.D., L.R.C.S.
PETER BUCHAN, M.B., L.R.C.S.E.

Kelso: August 18, 1869.

EDINBURGH ROYAL INFIRMARY.

At the meeting of the managers on the 26th August, a letter was read from Mr. Syme, resigning his post as one of the acting surgeons of the hospital. The managers received the resignation, and unanimously adopted the following resolutions:—

“That the managers of the Royal Infirmary receive with much regret Mr. Syme's resignation of his office as one of the acting surgeons of the hospital, the duties of which office he, during his long and brilliant career, has performed with so much benefit to the patients, and with so much honour to the Medical School of Edinburgh.

“That the managers, being anxious that Mr. Syme should still remain connected with the hospital, request that he will accept the appointment of one of the consulting surgeons.

“That an excerpt from the minutes, embodying these resolutions, be transmitted by the clerk to Mr. Syme.”

FRANCE.

A MEDICAL TRIP TO PARIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

PARIS, August 20, 1869.

DEAR SIR,—With your permission I beg leave to lay before your readers the results of a few observations made by myself during a short trip in France and a week's visit to the Parisian hospitals. On landing at Boulogne-sur-Mer, a few weeks ago, I was informed that the hospital at Berk ought to be visited by all medical men interested in questions of hygiene; and on inspection of this hospital, I found report to under-estimate the magnificent character of this charity.

Berk-sur-Mer is situated at some thirty miles distant from Boulogne, about seven miles from a station on the Chemin de Fer du Nord, called Montreuil-Verton. Berk is in the midst of a sandy desert, reminding me somewhat of New Brighton, near Birkenhead, except that there is no town there, but only about some 90 or 100 cottages and Swiss chalets, inhabited by summer visitors, who bring with them their own sheets, &c., and walk about bare-footed all day in the sand, bathing from their own houses, too, as there are scarcely any bathing machines. From the fact of there being no town to pollute the sea at Berk, the site seems admirably chosen for the magnificent

hospital for scrofulous children which, at the instance of Eugenie, has recently been erected and opened there. This hospital is a very large one, and is constructed to contain, when full, 800 children affected with scrofula or rickets.

At present there are not more, I should think, than 300 or 350 children there. The Sisters of Charity, and other employes, amount to 200 persons. The building is in the form of two long pavilions, with windows on both sides of the wards. The girls' pavilion faces the sea: the boys' pavilion is parallel to it. Two low sheds complete the building, forming, with the pavilions, a hollow square of immense extent. The hospital was opened formally by Eugenie in July. The pavilions consist of two storeys above the basement, both fitted up as wards, and there is also a ward in each basement, as also wards for infants nicely fitted up with cot beds. There is an infirmary too; but, at the time of our visit, all the children were walking about, and it was empty. The dress of both boys and girls consists, in summer, of blue cotton stuff, and, like the rest of the world at Berk, they seemed all to be bare-footed,—a rather harsh treatment, as it seemed to me, for such distressing cases of scrofula and rickets as I saw among the poor children. The beds in the wards were admirably constructed for hygienic purposes, almost entirely of iron. In July there was on each bed two sheets, and a blanket, a bolster, and a palliase, which rested upon wire springs, thus securing air both below and above the patient. The wards, to the number of 14, have each 36 beds, and each bed occupies 40 cubic metres of space. The air was perfectly pure, and without smell when I visited them at 10 a.m. The Infirmary wards have 16 beds in each, 80 in all, with 40 cubic metres to each bed. There are two gymnasia for the children. A pipe, 900 metres in length, brings water to the sea baths contained in the establishment, and there are various kinds of hydropathic baths also on the premises. The weak point in the administration seems to be the difficulty found in obtaining sufficient supplies of fresh water. This fresh water is derived from the layer of rain water, which filters through the sand on which the hospital is built, and lies above the denser sea water, which also filters through the sand. If too much water is pumped up it is, of course, not unlikely to be brackish, and this, it seems, is complained of.

On the ground floor of the pavilions are class rooms for the patients—first and second class, both for boys and girls, and lessons go on simultaneously with sea bathing and open air exercise. I peeped into one of these, the *école primaire*, and saw a bare-footed young *Seur de Charité* instructing a number of poor boys, whose sad sickly faces might remind readers of Dickens's works of the school in Yorkshire held by Mr. Squeers. I saw a number of the patients returning from their morning sea bath, and could not help thinking that if any place could cure such desperate cases of hip-joint disease, of disease of the ankle-joint, &c., &c., it was this charming sea residence. The funds for the construction of this hospital have been furnished by the city of Paris "Assistance Publique," and I hear that it cost about two millions of francs, or about £50,000 sterling, but for the accuracy of this statement I cannot vouch, as it was not printed. Before I close this description of Berk, I may mention that it seems to me to be an admirable resort for real invalids. There are no distractions, and no means of dissipation,—nothing but the sea air, bathing, tranquillity, and freedom from the toils of the toilette, which to the real invalid would render this place much more valuable than its more exciting neighbour, Boulogne-sur-Mer. Cottages, with about five rooms, can be hired by the week at about 50 francs, I was told by a gentleman proceeding thither with his wife, children, and "bonne," or servant. This gentleman, a resident of Amiens, preferred the life at Berk to that of any other bain de mer on the coast, when, with his family, it being, he observed, much healthier and economical.

From the same gentleman I had a stirring description of the fearful days of the cholera at Amiens in 1866. He

described how many of his friends had died of that terrible visitation. So dreadful was the depression of trade caused by the deaths (120 a day at the worst, in a population of 40,000) that he at length preferred going to Brussels with his family, in order no longer to hear of the death of his friends. I visited Amiens, and walked through the streets near the Cathedral and the Place du Périgord, and I will only remark this, that if Amiens desires to escape another visit from that terrible school-mistress in the art of hygiene, cholera, it will do well to wash itself; for of all the filthy towns in England and France that I have seen, none is worse than this. In passing, I cannot help remarking how little modern industrialism has, as yet, done for the condition of the workman in such towns as Amiens, Manchester, Liverpool, or other great manufacturing centres. In no town can there be more beggars than I saw in Amiens, in no town is there more misery than in these hives of human wretchedness. I spoke on this subject with my friend from Amiens, and he replied to my observation, that poverty was the cause of epidemics, "Mais, Monsieur, il nous faut des pauvres." You will thus perceive that, even in France, the "base doctrine," as Mr. Mill calls it, that poverty must always exist, finds advocates.

I explained to that gentleman that in many of the new States of America there was no poverty, and that France had less of it than England; and I said that, in my opinion, this arose from the fact that the population in France, as a whole, was stationary, although this was far from holding good in industrial towns such as Amiens, Arras, &c., where the workpeople, being unable to calculate for the future, were improvident as to the number of their families, and, therefore, sunk in abject poverty. I found that this gentleman, a considerable exception to the general rule, held that large families were happier than small ones in his experience, so that there is not that unanimity in France as to the theory of over-population, which we might well expect from the fact that the families are so small.

It appeared to me that the city of Amiens might easily be drained and rendered wholesome, if it but contained men of public spirit enough to study their money-bags a little less and their health a little more. Boulogne has set a good example; but then the Maire is a physician. The latter town is now infinitely cleaner than Amiens, and far cleaner than it used to be a few years back; indeed, it is the queen of "bains de mer" in France. The hospital of Amiens, too, is situated in a most miserable and infected quarter of the town, and, indeed, with the exception of the Cathedral, Amiens in the eye of the medical man cannot fail to leave a most painful impression as to the amount of supineness in matters relating to health still existing among our industrial magnates.

I propose in my next letter to offer a few remarks on what I observed at the Hôtel du Midi at Paris, at the Charité, and at the Hôtel Dieu and Lourcine Hospitals.

I remain, cher confrère,

Yours very faithfully,

CHARLES R. DRYSDALE.

FORCED AND PROLONGED FLEXION OF THE LIMBS IN TRAUMATIC HÆMORRHAGE.

M. von Adelman, of Dorpat, in a paper laid before the Belgian Academy of Medicine, and founded upon ten cases occurring in his practice, arrives at the following conclusions:—1. Forced flexion is a valuable means of arresting traumatic hæmorrhage. 2. It should be employed before having recourse to other hæmostatic agents. 3. It may be resorted to in cases in which ligature of the artery has failed. 4. A knowledge of its mode of application should be popularly diffused, so as to allow of its being at once adopted while awaiting the arrival of the surgeon. 5. Such knowledge may also be very useful in armies. 6. It is very desirable that manuals of surgery should bring the subject into prominent notice.—*La Presse Belge*.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 195.)

In answer to those gentlemen who are perfectly satisfied with the state of the Dublin Lying-in Hospital, as well as those who have so strenuously and unmeasuredly attacked me for attempting to introduce such improvements into its construction as will lessen the mortality within its walls; let me ask you—some of whom have even had the hardihood to assert that it is, quoad its mortality, in a satisfactory and improving condition—let me ask you, I say, to look at the facts. The institution has had out of the 113 years passed since its foundation, 65 years in which it was so severely attacked as to bring the death-rate, upon the rough principle of calculation given in my paper, from 3 to 2 figures, and thus 113 divided into the following periods show with what results:—In the first 18 years after the establishment of the hospital tested in this way, metria prevailed extensively in 13; in the next 20 in 7 years; in the next 20 in 8 years; in the next 20 in 8 years; in the next 20 in 13 years; and, in the last 15 years, in every year of the 15, or, in the last 35 years in 23 years, leaving only 7 years free from the ravages of the disease, as thus tested. To this length I was prepared to go, on writing my original paper, and to leave the comparison of two or three figures as the test of the existence or non-existence of metria within the walls of the hospital. The violent and multiplied attacks to which this has exposed me have naturally required my closer and more searching investigation of this subject. The conclusion which this reconsideration has led to, and confirmed, in my mind, is, that in this rough way of testing the existence of metria by the death-rate amounting to two figures in place of three, I was quite wrong and under the mark. That it affords no true test, and that I must abandon it in favour of a more accurate and trustworthy comparison. This I shall be obliged to develop and amplify in dealing with Dr. Beatty's paper a little later, and merely allude to this at present to prevent misapprehension.

We have seen that the condition of atmosphere which predisposes to this disease, is, at times, of very slow development, or what we term cumulative, in its properties. When these properties are thoroughly fermented—this phrase is not mine, Sir, it has been used by my critics—and right or wrong in its physiology, it describes what I want to convey. Then, there is often an equally remarkable rapidity in the time occupied in infecting its victim. But when it has once shown itself, then the law of my fourth proposition comes into operation—the law of habitat; that law which fixes its endemic character, by which the atmosphere is changed from its cumulative to its actual poisoned, or saturated, state. What was an approximation to it, during its cumulative period, becomes now an absolute fixed quantity; and so persistent is it, so obstinate and so pervading, that for weeks, months, and years, as I have proved to you by the history of the Lying-in Hospital, every part of the numerous and spacious wards of this institution has been haunted and occupied by this dire disease. That haunting and occupation has continued, until, like other zymotic diseases, it has worn itself out, or until it has been checked by want of victims; the patients not been admitted into the hospital, offering often the only effectual check to its continuance. One reason why the term habitat is especially applicable to metria is the peculiarly obstinate and pertinacious character of its hauntings, as compared to other zymotic diseases. In

cholera, measles, whooping cough, erysipelas, and even small-pox, the disease runs a course and terminates in a reasonable time. It may, in most of the epidemic attacks as they are termed, very questionably I think, be traced to its introduction into a house or neighbourhood hitherto free from it, from a house or locality in which it prevailed. It runs its course—precautions are taken—it wears itself out. The same is observed in epidemic prevalences of puerperal fever, where it prevails in districts. In these it runs its course very much as the other zymotics do; but it is not so in hospitals. Here the law I dwell upon, that of habitat, comes into operation, it continues to haunt the now infected hospital for an indefinite period. Why? Because *here* it possesses the conditions ready for its spread when in existence, and for its regeneration and cumulation, if suspended for a time in its ravages. These are the considerations which justify and require that ill-constructed Lying-in Hospitals should be denominated the habitat of puerperal fever. Need we again recapitulate the proofs of this adduced so often, but especially in treating of my third proposition? where I showed, amongst other instances, the deaths of 110 women in Dr. Collins's first four years' mastership, including some months of Dr. Pentland's, and 170 in my own seven years' mastership.

This consideration of the habitat, so conclusively proved, brings us, by a natural transition, to the more recent phase or change in the history of the Lying-in Hospital of Dublin referred to, and which embraces the last 35 years. In this period the principles of cumulation and habitat may be said to have culminated and become persistent. In place of occasional outbreaks of metria, with years of health, matters have changed.

This increase, or rather persistency of metria, would lead to the conclusion that true metria is changing in its character more and more every day, assuming the habits and laws of an endemic or indigenous disease in our great hospitals, which, instead of showing itself at intervals, as do other epidemic diseases, remains constant, and will continue to do so as long, at least, as those conditions which generate, cumulate, and develop it are permitted to exist.

This is the state of facts with which we now find ourselves face to face. The phase, the habits, the laws of metria are altered. The bygone history of the lying-in hospital is only so far of value as it traces out the progress of matters to this summation. We have now not an occasional epidemic, but an established disease, having its generating cause, its cumulative cause, and its pabulum within the four walls of the hospital. The hydra is there within your reach. Deal with it as you would with any other "pest-house." Again, Sir, this is the language of my critic, not mine. But, Sir, do not misunderstand me. I am in this question, at least, a reconstructive, not a destructive reformer. The disease, bad as it is, is not in a state to require either disendowment or disestablishment. It merely requires that the hospital should be modified to meet our improved knowledge of zymotic diseases, and the altered characters of metria in particular. Let the success of Joseph Clarke in trismus, and of Jenner in small-pox, encourage you in your efforts. Be not deterred by opposition. No valuable improvement was ever accomplished without it, and there is no abuse so untenable that it won't have its backers, no fallacy so palpable that it won't have its supporters. Jenner was nearly annihilated by the anti-vaccinators; he survived them, and the anti-vaccinator is now reduced to a unit. Our profession, enlightened and humane as it is, is not easily turned out of its habitual course of thought and action. Besides, the attractions to our revolving in our present path of thought and action in the case of our large hospitals are weighty and cogent. Let us not, however, try this out too long, or add a third case to the two instances that give the death-rate of the Dublin poor management an infamous celebrity, and one handed down in

the statistical books of the last half century as a disgrace and blot to our national character. Let the infant parish mortality and the death-rate of the foundling hospital remind us that, not many years since, there were respectable men, and wise heads, aye, and learned doctors, who did not flinch from maintaining and advocating the persistence in a system of mismanagement, the results of which are too disgraceful to dwell upon, and which led to the erasure from our charitable institutions of one which was at that time, what the Dublin Lying-in Hospital has been, the pride of this city—an institution which, with proper management like similar institutions elsewhere, might have been rendered a means of combining a charitable ministration, with a powerful engine of civilization and enlightenment throughout this country.

Sir, I now approach a branch of my subject that I would willingly have avoided. Dr. M'Clintock has detected an error in my transcription, and this is at once characteristically denounced as follows:—"Here Dr. Kennedy has committed a serious arithmetical mistake in his data, which consequently falsifies all the conclusions he has laboured to draw from them." Now, when I tell my hearers that this statement is the substitution of thirty years for twenty-three years in transcribing from Dr. Elliott's book, the period for which an average calculation was adduced; that the result was strictly correct in the average as the basis of calculation founded on the twenty-three years' period; but, above all, when I tell them that the error in transcription was itself corrected, in the same page, by giving Dr. Elliott's text *in globo* in which the two periods were fully set forth, and the calculations based upon them detailed by Dr. Elliott himself, I think I am justified in asking whether it was a worthy or justifiable line for an honourable antagonist in argument to take, to put into circulation an assertion that "I had committed a serious arithmetical mistake in my data, which consequently falsified all my conclusions," knowing that for weeks or months this damnatory misrepresentation must be in circulation before its contradiction should appear? It will be recollected that Dr. Elliott, in his report of the Waterford Hospital, mentioned that after six years, for which his hospital was established, he removed to another building; and he gives the statistics of this hospital separate from the one he removed to. The statistics of the latter, extending over a period of twenty-three years, I, Sir, of course, took the longer period for the basis of my calculation; firstly, because it was the longer period, and secondly, because there were fewer beds in the wards, and it consequently approximated more nearly to my idea of a cottage hospital. In the hurry of transcription I gave it in my last as the result of the thirty years, not the twenty-three years' period. In the table of figures in the next page (304) I give the accurate result on the twenty-three years calculation, namely, 1 death in 259, and this it is that forms the basis of my calculation. It is therefore perfectly correct, and I repudiate entirely Dr. M'Clintock's figures, based upon a total different calculation. It is a remarkable fact that by a typographical error a unit is omitted in the same paragraph that Dr. M'Clintock deals with, but he did not deem it necessary to dwell upon this, as the omission told 1,000 against my argument.

Good, however, comes out of evil, as Dr. M'Clintock's delicate exposure of "my serious arithmetical mistake and falsified conclusions" has drawn out a further commentary from Dr. Elliott, who writes to me to this effect:—"But the most useful and instructive mode of viewing these statistics is reached by dividing them into two periods. During the first period of six and a-half years we occupied an hospital in which eight beds were grouped together in one ward, and there during that period the total mortality was 1 in 125½, and the mortality in puerperal fever was 1 in 251. During the recent period of twenty-three and a-half years we have occupied our present

hospital, in which eight beds have been divided between two wards, four beds only in each ward, and here we have had a gross mortality, from all causes, of 1 in 309, and a mortality in puerperal fever of 1 in one thousand three hundred and ninety." Dr. Elliott considerably adds, "I use letters instead of figures, that there may be no mistake this time."

If further proof were required of the too palpable conclusion of the rate of mortality being in proportion to the number of patients occupying a given space, as insisted upon in my third proposition, so violently attacked as the Redan of my position, what could more completely resist their assault and turn their attack than the simple, wise, and thoroughly trustworthy statement of Dr. Elliott, that by the mere expedient of reducing his beds from eight in one ward to four in his two wards, he succeeded in reducing his gross mortality from 1 in 125½ to 1 in 309?

This admits of no refutation, and requires no comment beyond what Dr. Elliott states in his pamphlet, page 6, as a significant fact, "that whereas the mortality from puerperal fever was in the first hospital 1 in 251 during a period of six years and six months, the mortality from the same cause has been, in the present one, only 1 in 1,328.

Dr. M'Clintock's best specimen of statistical criticism remains. It is that in which his anxiety to arrive at truth is only equalled by his determination, in his own language, "to show my chain of reasoning fallacious," "inasmuch as a great error, represented by the number 8,688, lies at the very basis of my calculations, and vitiates all the conclusions derived from them." The error is this: I give the total number of births in the Dublin District for the period specified as 52,126, whereas it is only 43,438." Dr. M'Clintock then naively adds—"I discovered this by the merest accident in the library up stairs when looking over the reports of the Registrar-General for Ireland;" and then, feeling that he has gone to the very verge of the line of veracity in his insinuation, adroitly turns the subject with the most inimitable simplicity by the words—"Let me now return from this digression." Now, let me ask, if the object of these remarks was fair and candid criticism, why did not Dr. M'Clintock show to his hearers how this mare's nest of 8,688 of an error vitiates all or any of the conclusions derived from this calculation? Simply because he could not, as the calculation was not in the slightest degree affected, nor the results in the most remote degree influenced by the mare's nest he had discovered. Dr. M'Clintock knew when he had penned this that I was discussing an average from these figures, add that whether this average was produced from forty or fifty thousand did not signify. Hence, then, the graphic description of the "accident in the library when looking over the reports." I had nearly forgotten to add the interesting detail, following the example of Mrs. Quickly and her seacole fire, in order to insure precision and extreme accuracy. Dr. M'Clintock informs us that it was "upstairs;" and hence, also, the sudden and adroit, but, alas! now that the day of *reckoning* has come, the simple suggestion, "Let us return from this digression," will not avail in relieving him from his dilemma when I tell him, as I do, that the duty remained to him to prove in what manner the 8,688 "had vitiated all my conclusions." Sir, that was a duty he could not execute, because it was impossible for him, by any amount of ingenuity, to prove as a fact what was not a fact, and what he put forward as a fact, although the means of testing its falsity were before him "upstairs in the library," just as patent as they are before you and me at this moment.

The fact is, the 8,688 error was totally unimportant in transcription, and whether it was 8 or 8,000 did not affect the result one iota. You will perceive by this return, kindly furnished me by the Registrar-General for Ireland, and given beneath, that the total number of births are given in six consecutive lines of figures thus:—

	1864	1865	1866	1867	1868	1869, 5·8
Deaths from puerperal fever,	42	32	66	37	32	42
" in childbirth,	18	35	27	38	46	23

Average number

The first five take in the year, the 6th gives the average.

Now, the same table gives, over down, the deaths from puerperal fever and metria in consecutive years also, and with the average the last column, thus:—

Deaths from puerperal fever,	42	32	66	37	32	42
" in childbirth,	18	35	27	38	46	23

In transcribing the above numbers into a column for totting, the sixth line of figures was added in both cases from the words "average numbers," written in a small hand, causing them to escape my notice. Thus the average of births was given as an additional year, as well as the average of deaths, leaving the resulting average, which was the object of the calculation, identically the same as if both had been omitted, and the five years only given. This, then, is the great error discovered upstairs in the library, that "renders my whole chain of reasoning fallacious, and vitiates all my conclusions."

But, Sir, as this great error has been mooted in all the medical coteries of Dublin, and will fly over medical Europe on the wings of the press, I have deemed it due to myself and to the important subject into which I have thrown my advocacy, to place these *great errors* of transcription, so much much dwelt upon, in their right light. I have, therefore, required the certificate of Mr. Francis Low, whose reputation as a notary public and statistician rank so deservedly high as to their true nature and their bearing upon the subject under discussion. Here is his certificate:—

"At the request of Dr. Kennedy I have examined his computation of the rate of mortality from puerperal fever and childbirth which prevailed in the Dublin registration district during the five years from 1864 to 1868 inclusive, as given in his paper on 'Zymotic Diseases,' and deduced from the Registrar General's return, and find that, notwithstanding an error in the transcription of the figures, *the result is correct*, as will be seen by the following explanation:—

"Dr. Kennedy, in summing up the total number of births, as also of deaths (resulting from the causes stated), for the five years alluded to, included, in error, a sixth quantity, viz., the average for the five years, which had been placed in a sixth column over against the other five, giving the births and deaths referred to. The including of this sixth quantity, though inadvertent, *plainly cannot affect the result*, because *it is the mean (as stated) of the other five, and therefore the mean of the six must be identical with that of the five, and the mean number of deliveries, divided by the mean number of deaths, constitutes the rate of mortality sought.*

"Dr. Kennedy also quotes correctly Dr. Elliott's report of the rate of mortality (1 in 295) prevailing in the hospital in Waterford intended to be referred to, viz., that occupied as such from October, 1844, the only errors being the statements that Dr. Elliott's report regarding the mortality in this hospital extended from 1838 to 1863, instead of from 1844 to 1867, and that the mortality from puerperal fever was 1 in 328, instead of 1 in 1,328, which latter rate manifestly strengthens Dr. Kennedy's position.

"FRANCIS LOW, Not. Pub.

"DUBLIN, 26th June, 1869."

(To be continued.)

THE Poor-law Board has expressed an opinion that in consequence of pending changes in the constitution of the union, it is inadvisable for the guardians of St. Margaret's and St. John's, Westminster, to increase the salary of their medical officer, Dr. Bond, as they desired to do. The Board advises that the guardians should make some temporary arrangement as to the cases to be attended to by Dr. Bond.

Correspondence.

TO THE EDITOR OF MEDICAL PRESS AND CIRCULAR.

SIR,—I think the following case is of special interest just now, as bearing on the point of the alliance between puerperal fever and scarlatina:—

I was called about three months ago to attend a woman, aged thirty-five, in her confinement with the fifth child. When I got to the house I found three of her family laid up, in the same apartment with herself, suffering from scarlatina. I immediately ordered them out of the room, and mentioned to her husband and friends the great danger she was in of contracting this disease, and told them if she did there would be very little hope of her recovery.

On examination, I found the os uteri very little dilated (though, as she said herself the *labour was on her* for three days previously); the vagina hot, just as if there had been pressure on it, and that the labour pains had ceased. As I had another engagement to attend to, after giving the necessary directions, and ordering them to send for me when the labour got stronger, I left. On the following morning I was hastily summoned to her. I then found that the labour had proceeded to the second stage, and I had not long to wait till the child was born. The third stage was a little tedious; but by pressure over the fundus utero, at the end of three-quarters of an hour the placenta was expelled. I then bandaged her, after which she said she never felt stronger after any confinement. She continued well up till eleven o'clock of the same night, when, as they said, she was attacked with pains and cramps in the stomach and legs, which were shortly followed by diarrhoea, which continued up till six o'clock on the next day, when they again sent for me. When I then saw her it was evident there was not a chance of her rallying, for she was so prostrated as to be unable to turn in bed. The pulse was excessively quick; the extremities cold; the skin was of a dusky-yellowish hue; and she was scarcely able to articulate a word. I ordered her some brandy and ammonia, with heat to the extremities; but she died the same night about midnight, only having survived twenty-four hours from the first appearance of the symptoms.

I think, Sir, it may be fairly presumed that this woman, as she never had scarlatina, died from the absorption of the scarlatinal virus; yet how different were the symptoms from those of that disease, and how like those of puerperal fever!

Your obedient servant,

WILLIAM STEPHENS, M.D.,
Medical Officer, Dunkineely Dispensary.

Dunkineely, Co. Donegal: August 27, 1869.

UTERINE RHEUMATISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the queries of your correspondent, "Azygos," will you permit me space to say that, in the treatment of uterine rheumatism, I have found extract of belladonna, diluted with glycerine, locally applied—this covered with silk paper, and a warm poultice or gutta-percha pline covering all—a preferable remedy to the liniment mentioned by your correspondent, and that, most assuredly, I would prescribe the exhibition of tincture of aconite in the attritic mixture.

I am, Sir, your obedient servant,

J. WARING CURRAN.

Osman House, Sutton: August 27, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wonder greatly if any of your numerous medical correspondents could explain the following, taken from the *Irish Times* of Thursday, 26th inst., relative to an inquest that was held at Waltham, a small village about seven miles from Canterbury. Fourteen persons partook of poison of some sort, and the following is the medical testimony:—That a *post-mortem* examination of the bodies revealed the fact that death had resulted from arsenic taken in a diluted form, or

what is called "corrosive sublimate." There is evidently a mistake on the part of some person, for I can scarcely credit that any medical man would be so grossly ignorant as to confound arsenic and corrosive sublimate, or to have so far forgotten his chemistry as to imagine that any acid secreted in the stomach would convert As_2O_3 into $HgCl$.

Excuse my taking up your space with so trivial a matter, but, as it might lead people astray, I thought it just as well to draw your attention to it.

Your obedient servant,

WILLIAM BULL.

Nenagh : August 28, 1869.

THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last issue I very much regret to find that Dr. O'Flynn labours so hard to impress on your readers the advisability of a *Medical Triumvirate*, which, he proposes, shall reign and rule over medical destinies.

I am rather of opinion that very few brother professionals will be found to countenance or to support the proposition, the Profession being determined to insist on, and to carry to a successful issue, that clear, concise, and consistent plan, yeleft representation, so fully discussed in the columns of the PRESS and other journals. Undoubtedly, the Medical Council is little better than a farce; but farces generally have point in them, and in this instance clearly "point a moral," which is, that had the promoters of the Medical Council Act, ere that measure became law, laid a good foundation on which it might rest—by first securing a *State Qualification Bill*; and, secondly, causing to be elected from amongst graduates, members, &c., of the several college representatives—that "august" body might now be to the Profession as a tower of strength, instead of the disjointed, disorganized, fragile "structure" that the most staunch and sincere of its friends now candidly acknowledge it to be.

To Sir John Gray, Dr. Prosser James, and others of like calibre, the Profession now hopefully look. Sir John Gray is not the man to overlook the "moral." Be assured he will start a structure on a sound base, and raise it, broad and towering, durable and mighty, worthy of this age of progress—worthy of the holy mission of medicine.

Faithfully yours,

R. L. JOHNSON.

London, N.W. : September 3, 1869.

Gleanings in Medicine, Surgery, and the Allied Sciences.

THE THERAPEUTICS OF WAKEFULNESS.

Brushing the hair or friction of the skin, as by rubbing the palms of the hands or backs of the arms, will in some persons tend to induce sleep. Soothing sounds have a similar effect, while, on the other hand, persons whose occupations are noisy are apt to awake when the noise to which they are accustomed suddenly ceases. But agents more efficacious than such external ones are those which lessen the amount of blood circulating in the brain. First may be mentioned food and drink, of whose happy influence a frequent illustration is given in the case of a late supper. During digestion more blood circulates through the gastro-intestinal vessels than when the abdominal organs are unemployed; and this additional amount of blood must come from some other part of the body, since a marked excess of this fluid cannot exist in two different parts at the same time, except in cases of disease. That the amount of blood in the brain is diminished during digestion is evinced by the feeling of drowsiness commonly experienced, which is a perfectly healthy sensation. The food thus taken as a therapeutic agent should be easily digestible.

In persons weak or anæmic, especially women who have been rendered so by hemorrhages, a dose of some of the preparations of alcohol at bedtime is frequently advisable. Of these,

wines are not so generally admissible as spirits. A clergyman who came under my care had been unable for seven or eight weeks to sleep more than two hours each night. I prescribed a dose of whisky, to taking which he at first strongly objected. The first night he slept five or six hours, and the second seven or eight hours. His whisky was gradually reduced from half a glass to none at all, and he continued to sleep well without having formed any habit of drinking. In some persons coffee acts much as other stimuli do in asthenic cases. Do not trifle with it by administering a little weak infusion, but give strong doses at once. Much depends upon the method of making it. Exhaust the strength of three or four ounces of ground coffee by percolation with a rather small amount of boiling water, and give it without milk. Tea acts in a similar manner, but not so efficiently.

Sometimes sleep may be produced by exercise taken regularly about two hours before bedtime. This acts best in asthenic cases. It has often been noticed that change of air and carriage exercise produce sleep. The warm bath may be used as a hypnotic, but the head should be prevented from becoming heated by putting cold water on it while the body is immersed, and sometimes cold water suffices without the bath. Another remedy, often of much value, is the application of a sinapism to the epigastrium. The position, too, of the body is of importance. In many cases, holding the head downwards produces wakefulness, and such persons should go to sleep in the erect posture. Amongst drugs, opium is hypnotic in doses of one or two grains, and one of its constituents, narceine, has been found to produce continuous and profound sleep: but the ordinary preparations are too uncertain to be relied on, and it is too expensive for frequent use. Hyoscyamus sometimes acts excellently, having the advantage over opium of not producing headache and constipation. The tincture, especially Neergaard's, may be given in doses of a drachm to a drachm and a half three times a day, if necessary. Oxide of zinc may prove serviceable in some cases, two grains being given three times a day. When much larger doses are given, it generally produces irritability of the stomach. Phosphorus is a remedy which has come into use recently. Twelve grains of phosphorus should be boiled in one ounce of almond oil, and filtered. The oil absorbs four grains of the phosphorus, so that each minim contains 1-120th grain. Half an ounce of this oil is to be mixed with one ounce of gum arabic, and fifteen drops of some aromatic oil are added. Of this mixture the dose is fifteen drops, equal to five drops of the phosphorated oil, and containing 1-24th grain of phosphorus. I have used it in eight cases with success, and failed in two cases. I try to get three doses taken before bedtime, and thus far have succeeded in producing the desired effect on the second day, if I had not on the first. The dose may be increased by a drop a day until twenty are taken or signs of gastric irritation supervene. But of all the sleep-producing agents at our disposal, bromide of potassium is most deserving of the name of hypnotic. I have never seen it fail when given in sufficient quantity. A healthy adult may take from twenty to thirty grains three times a day, the latter dose not being too large when needed at all. Sometimes it produces, amongst its other effects, great weakness in the legs and a staggering gait, strongly resembling that of a person intoxicated with alcohol. It also occasionally produces great lowness of spirits and a disposition to cry. It should be administered very much diluted, and may be conveniently prescribed one ounce in four ounces of water, a drachm of this being given in at least half a tumbler of water.—*Boston Journal*.

THE STETHOSCOPE.

Dr. Paul Niemeyer, of Magdeburg, calls attention in the *Deutsche Klinik*, Dec. 5th, to the discrepancy between the theory and practice of Laennec. His theory was that the scratch of a needle on one end of a long beam could be heard by applying the ear to the other end, and that this depended upon the conduction of sound through the solid medium. In practice he used a roll of paper, subsequently a hollow wooden cylinder; that is, he used a medium of wood and air in ausculting.

Now it is an established fact that wood is a better conductor of sound than air; pine wood, according to Chladni and Lavart, conducts sound eighteen times better than air.

Niemeyer asks: why do we, in the ordinary stethoscope substitute a notoriously bad conductor for one notoriously good? In other words, why do we make that useful instrument hollow? He recommends the use of solid stethoscopes,

made of that variety of pinewood which is used for the sounding-boards of musical instruments. The ear-piece must be in one with the body of the instrument, and not screwed on.

POISONING WITH OPIUM, AND ITS PREPARATIONS.

The *Journal de Chémie Médicale* publishes the statistics of 404 cases of poisoning by different substances, extending over a period of eleven years—1855 to 1865, inclusive. The deaths from arsenic numbered 135; from phosphorus, 180; verdigris, 15; sulphuric acid, 22; sulphate of copper, 63; cantharides, 10; but only 6 from laudanum, and 1 from morphia. [A few years back, in England and Wales alone, 640 inquests were held on persons who had died from poisoning: of this number, 194 were cases of poisoning by opium or its preparations,—viz., 133 from laudanum, 42 from opium, 12 from Godfrey's cordial, 5 from syrup of poppies, and two from mixtures containing opium. In this colony, deaths from laudanum are not infrequent. In France, the sale of opium and its preparations is controlled by law. In this country there are no restrictions on the sale of laudanum and opium. The consumption of chlorodyne in the colony is very great, large quantities being taken secretly by females as a substitute for drink; and many cases of poison occur from it without being recognized.]

POISONING BY PUERPERAL BLOOD INJECTED INTO THE VEINS OF ANIMALS.—BY M. COZEL.

Three rabbits inoculated with puerperal blood died with convulsions and spasms of the respiratory muscles, as if from strychnine. Two of them uttered plaintive cries before death, like animals inoculated with putrid blood. He states that he never saw the same effect produced by inoculation with the blood of patients suffering from scarlet fever. The puerperal blood taken from different parts of the body showed, under the microscope, an augmentation of white corpuscles; the red globules, generally altered in shape, exhibited an abundance of fibrinous tracks. The lungs were dark-coloured, and in places ecchymosed; they presented more resemblance to the state observed in asphyxia than in inflammation; no signs of the latter could be discovered by the microscope. The spleen was dark-coloured, and gorged with blood, which presented all the alterations mentioned above. These were the only organs altered.—*Gazette Médicale de Strasbourg.*

BRAZILIAN ANTIDOTE AGAINST THE BITES OF VENOMOUS ANIMALS.—BY DR. CASTRO.

There is a plant in Brazil called Paracory, which the doctor believes to belong to the *labiate*, and which has long been considered an antidote against the poison of insects, snakes, and fish. It is made into a tincture and applied to the bites, and given internally. He found it of service in diseases of the skin, and for increasing the efficacy of mercury in syphilitic diseases, and a powerful sedative in whooping-cough and asthma.—*Gazette Médicale de Bahia.*

CONSUMPTION IN BRAZIL.—BY DR. WUCHERER.

From this gentleman's researches it would appear that consumption, particularly at Bahia, has been increased by the introduction of strangers, by the crowding of people into the towns, and the drinking large quantities of spirits and fermented drinks. The increase of smoking he considers a cause of this disease. When Brazil was only colonized by Portuguese, the number of deaths from phthisis did not exceed those which occurred from this disease in the mother country. The introduction of other immigrants, particularly Germans, and the admixture of African blood with the European, produced a great tendency to this disease.—*Ibid.*

CASE OF ACUTE PHLEGMONOUS OSTEO-PERIOSTITIS OF THE RIGHT TIBIA—DEATH ON THE THIRD DAY.—BY DR. BECKEL.

The patient, a strong healthy lad, aged twelve years, struck his leg slightly while dancing. The next morning, on attempting to rise, he felt great pain in the upper part of the tibia; slight swelling was observed, and some fever. Five leeches were applied. On the second day the swelling had extended down the whole length of the tibia, with great heat of the part, and there was slight delirium. By the third day the pulse had risen to 120; skin hot, with great swelling of the tibia. The slightest movement of the limb caused him to utter loud cries. In the evening he became insensible and pulseless. An incision was made down to the bone; a little blood flowed, but

no pus. He died a few hours later. When an incision was made through the periosteum, a large quantity of reddish sanious fluid escaped. The tibia was separated throughout from the periosteum, except at the junction of the shaft with the head. The bone had a marbled appearance, and in some parts there were traces of commencing necrosis. The medullary portion was yellow and fatty, and in two places small clots of blood were discovered. The rest of the body was not examined.—*Gazette Médicale de Strasbourg.*

Observations.—Acute idiopathic inflammation of bone is very rare, and books on systematic surgery may be consulted without finding any notice of it. Barwell, in his very valuable work on "Diseases of the Bones," describes the symptoms, and they closely resembled those observed in this case. "The bone," he says, "is the seat of intense pain and hard swelling; the skin is red, except when the bone is deep-seated, but it is always hot when the inflammation is extensive. The pain exhausts the patient, and renders him comatose or semi-comatose. Low muttering delirium appears early; the tongue is dry and brown; the limb is held immovable; the swelling becomes softer, and shows evidence of suppuration, and except when deep-seated, as at the femur, fluctuates."

The writer has seen it occur in connection with acute phlegmonous erysipelas of the thigh. In this case the muscles were softened and infiltrated with sero-purulent fluid; the periosteum was thickened and separated by a similar fluid from the bone, which was necrosed; the bone was injected and generally of the colour of port wine lees.

The lungs were infiltrated with dirty sero-purulent fluid; the cavities of both sides of the heart distended with fluid blood; the spleen diffuent, and the brain softer than usual. These were the chief alterations observed. The patient died asphyxiated.

The following case resembles the one published by Dr. Beckel, but it was traumatic, not idiopathic:—

A girl of the town, aged seventeen, was knocked down by a cab, and the tibia and fibula fractured. She was brought into the infirmary, and for the first four days did well. Fifth day, slight fever observed, the pulse had risen to 120, tongue coated, and face anxious. The fever increased, and, in the night of the seventh day, delirium and vomiting set in. The leg was very much swollen and tender, and when touched she uttered loud cries. The limb was placed on a cushion, and retained in position by sand-bags. The symptoms underwent little alteration; but coma, not very profound, alternated with delirium, which assumed a muttering character up to the tenth day, when the left elbow and right wrist were observed to be swollen. The tongue was coated with brown fur, pulse 130, feeble, eyes sunken and surrounded with dark circles, face of a leaden aspect, motions and urine passed involuntarily. She died in a state of coma the next day.

The soft parts were infiltrated with fluid, and, in the neighbourhood of the fracture, with sanious matter and some clots. The periosteum was separated from the tibia for some distance by sanious matter; the bone was roughened, its medullary surface was dark and softened; purulent collections were found in the lungs, liver, and kidneys. The pleuræ, pericardium, and arachnoid cavity contained sero-purulent fluid; the spleen was gorged with dark blood, and softened.

THE SEWAGE OF EXETER.

(From the *Exeter Gazette Daily Telegram.*)

WE have gone the round of the leats which wash the foundations of the dwellings of the people in some of the most densely populated quarters of Exeter. The heart sickens at the thought of what we have seen. The streams run thick and almost opaque with the foulest of pollutions, and the odours in the midst of houses are suggestive of pestilence. Take the leat at a point just below St. Bartholomew Church and the old Cemetery. The quick current comes clear and transparent from the Exe down to a certain bridge. There a gigantic sewer opens into it, emptying the filth from a district comprising a population of some twenty thousand persons. From that point through all its devious course to the river again the leat is foul beyond description, and it runs past the doors

of two or three thousand of our citizens, who complain bitterly of the stench in the midst of which they eat and drink and sleep. We saw a horse led into this leat near the mouth of the sewer we have mentioned, and the animal dipped its nose in the water and again and again refused to drink. It pawed the water with its forelegs, seeming to think it possible that the filth might be made to pass on and leave the water drinkable, but in vain. Then it turned upward, away from the mouth of the sewer, and reluctantly took a scanty draught. Twenty yards lower we saw a boy filling two buckets in the leat. We asked him, what he was going to do with the water, and he said it was for the use of the opposite houses, for the wells had run dry. The sewage from a population of twenty thousand people was running into this water, but the mouth of the sewer was on one side and the boy with the buckets on the other, and so on the right hand side of the stream the water looks comparatively clear, and on the left hand side thick and foul, for in twenty yards from the sewer mouth the foulness of the water is not uniform, and the stuff was not quite so bad where the boy filled his buckets as where the horse declined to drink. But the incident of the boy with the buckets was sufficient to enable us to form a faint idea of what we are doing when we turn an open river into a common sewer. When a drought comes and water runs short, and the stream is unusually foul, the people send their buckets and supply their houses with the fluid, slightly diluted, which comes direct from the water closets of the city. We followed the various leats throughout their course to their outfall into the Exe. The journey is a loathsome one to make and disgusting only to remember. An unbroken column of foul stench marks the tracks of these streams into which the sewage is emptied, while the portions which deviate and do not carry much of the sewage are clear and apparently wholesome, showing what the leats might be but for the dreadful system which, at an ill-fated moment, was adopted by the local authorities of Exeter. We entered houses, warehouses, mills, and manufactories under which and through which those waters run, and the places were for the most part filled with a detestable odour, and the inhabitants and work-people complained of sickness and disease. This is not a very pleasant subject to talk about. We would prefer not to lay the nauseous story before our readers this morning, and we forbear to relate the sickening details, the recollection of which renders the very writing of this notice a most unwelcome exercise. It is enough to say that there can be no mistake about the pollution that permeates the water and the atmosphere about the lower ground of the West Quarter and its vicinity, and after seeing what we have seen we can only wonder at the beneficent qualities of the climate in which Exeter is situated that it so far counteracts the maleficent influences of our sewerage system as to reduce the surplus number of deaths in a year to 250. The only marvel is that the plague of two hundred years ago does not revisit us during the exceptional heat of these summers. Seeing these things it seems unreasonable to ask the city to wait for a scientific solution of a problem which the scientific appear to be no nearer solving than they were ten or fifteen years ago. London would wait no longer, and why should Exeter? For a definite sum, not by any means ruinous, the sewerage of the city might be carried away down to Exminster Marshes, or to some spot below the commencement of the canal, to be utilized, if utilization be possible, or to be cast into the broad river until agricultural chemists and engineers shall come to a decision as to what ought to be done with it.

Medical News.

CONTRIBUTIONS to the amount of £500 have been subscribed by the friends of the late Dr. Manning, of Wicklow, as a testimonial and tribute to his memory.

A TRANSLATION of Mr. Erichsen's work on the cerebral lesions depending on railway accidents, by Dr. Kelp, of Oldenburg, has appeared.

THE new chapel at the Devon and Exeter Hospital, which has been erected for the use of the inmates at the sole expense of Mr. Arthur Kempe, F.R.C.S., one of the honorary surgeons, was opened for public worship on Tuesday week. The cost is said to have been nearly £2000.

SEVERAL cases of cholera have occurred at Madras.

BY an Order in Council, just made public, the Queen has been pleased to approve the proposal of the Admiralty, "that for the future no Deputy Inspector General of Hospitals and Fleets shall be promoted to the rank of Inspector-General of Hospitals and Fleets unless he shall have served five years as Deputy Inspector, during three years of which period he shall have been in charge of a foreign hospital, or of a fleet or squadron."

A MEDICAL GENTLEMAN ATTACKED BY A COW.—On Thursday week, Dr. Fraser, of Paisley, was attacked by an infuriated cow, which knocked him to the ground, skinned the side of his head, and otherwise seriously injured him. The cow was being taken to the slaughter-house at the time. The Doctor is progressing satisfactorily.

INTERNATIONAL FLAG.—The consent of the French Government has been given to the hospital of Dr. Steinberg, Physician-General to the Prussian Navy, for the adoption of an international flag of distress. The document was inserted in the *Moniteur de la Flotte*.

Dr. TIMSON, of Greenwich, against whom a charge of malpractice had been brought, and at the trial the jury was discharged without being able to find a verdict, has been admitted to heavy bail, himself in £2,000, and the other prisoner, McGrath, in £1,000.

APPOINTMENTS.—Army Medical Department—Assistant-Surgeon Thomas Alexander Clapperton Macarthur, from Royal Artillery, to be Staff Assistant-Surgeon, vice Joseph Septimus Steward, who resigned July 8; September 1. Assistant-Surgeon Alexander Ferrier Churchill, M.D., from 31st Foot, to be Staff Assistant-Surgeon, vice James Hector, M.B., appointed to the 31st Foot; September 1. Assistant-Surgeon John Colahan, M.D., from 24th Foot, to be Staff Assistant-Surgeon, vice Eugene Valentine MacSwiney, M.D. appointed to the 24th Foot; September 1. Assistant-Surgeon Charles Haines, from 10th Foot to be Staff Assistant-Surgeon, vice Robert F. Buchanan, appointed to 10th Foot; September 1.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—At the meeting of this society, held on Friday, the 3rd September, in the Hall of the Faculty of Physicians and Surgeons, the following gentlemen were elected Office-Bearers for the present Session.—President, Dr. J. G. Fleming; Vice-Presidents, Dr. E. Watson, Dr. Steven; Council, Dr. G. H. B. Macleod, Dr. A. R. Simpson, Dr. Richmond, Paisley, Dr. F. Thomson, Mr. Torrance, Airdrie, Dr. H. Thomson, Dr. James Gray, Mr. Robert Grieve; Secretaries, Dr. James Adams, Dr. R. Perry; Treasurer, Dr. H. R. Howatt.

HARVARD UNIVERSITY.—Harvard was founded early in the seventeenth century at Newtown, one of the earliest pilgrim colonies, the name of which, after the establishment of the college, was changed to Cambridge. Among the settlers at Newtown were a number of graduates of old Cambridge, England, mostly alumni of that Emmanuel College which had been founded by Sir Walter Mildmay, in 1585, and which the maiden queen suspected, with her shrewd wit, to be a "Puritan foundation." These Emmanuel settlers in the new world set up a branch of their *alma mater*, which were at first Puritan indeed. The young college of New Cambridge received a grant of £400 from the General Court of Massachusetts, which was then considered an excellent beginning. In 1638 the Rev. John Harvard, a wealthy Puritan minister who had come over from England, bequeathed his valuable library and half his property to the infant institution. The gratitude of colleges usually takes the form of adopting the benefactor's name for some purpose connected with them, so Cambridge College became Harvard College. Harvard's example set the fashion: endowment multiplied, the magistrates of the colony gave £200 worth of books, and poor and rich contributed to help along an institution of which Massachusetts Bay was already proud.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 15, 1869.

STUDENTS' NUMBER.

IN our present Number we compress a mass of information for the benefit of Medical Students in the three Kingdoms. To enable us to do so, we are obliged to divest the regulations from much of their prolixity, but we trust that this process renders them rather more explicit than otherwise. Our STUDENTS' NUMBER is not for London alone, but for Great Britain and Ireland.

THE MEDICAL COUNCIL.

To this body is entrusted the supervision of medical education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a student of medicine, at the commencement of his career, at the office, Soho Square. It is to be hoped that the Medical Council will soon be reformed, and become an effective supervisor of medical education.

THE CAREER OF THE ENGLISH STUDENT.

THE young gentleman who is about to enter the Medical Profession in England has more than one course open to him, whether he decide on fulfilling his curriculum in London or in one of the provincial schools. The latter course is generally determined by local causes with which pupil and parent are both familiar. We propose, therefore, in this place, to point out a few things that concern the London medical student.

First of all, as to apprenticeship. The only English corporation that absolutely requires an apprenticeship is the Society of Apothecaries, which is bound by Act of Parliament. The clause, however, is very liberally interpreted, and the apprentice may, during his term, fulfil part or the whole of the curriculum. The master must possess the licence of the Company, but he may practise any department of the Profession. There is much difference of opinion as to the value of an apprenticeship. Some profess to despise it, and regard it as a badge of trade. There are, however, many advantages in the system, if carried out in the liberal mode we have spoken of; and we feel sure neither pupil nor parent would ever regret having entered into such an agreement with a medical gentleman of position and honour. Thus, suppose a pupil to be bound apprentice to a Licentiate of the Apothecaries' Company for a period of five years, with the right to attend lectures and hospital practice during the last three years, he enjoys the following advantages: In the early part of his pupilage he not only learns practical pharmacy, and becomes acquainted with the more generally used articles of the *Materia Medica*, but, if industrious, he may pass the Preliminary Examination,

Moreover, he prepares himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he has thus acquired will procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience is of the very highest value, should he decide on settling in general practice after he is qualified. On the whole, then, this modified apprenticeship system is equal to any, and parents who know a practitioner to whom they would willingly entrust their sons, cannot do better than pay him a fair premium. Those residing near will occasionally be able to arrange for an out-door apprenticeship.

Supposing, on the other hand, that the plan of apprenticeship be rejected, a young man may still become the pupil of some one in practice. This is often done by those who aim at the higher branches of practice. A physician or surgeon who will give some time to the superintendence and direction of a pupil's study certainly offers him great advantages, and those who can afford thus to act will not regret the expense of providing their sons with such a guide.

Lastly, a pupil may enter at any of the London hospitals without any such preparation. He has only, provided he has passed a preliminary examination, to pay the first year's fees, and he is admitted at once to all the dignity of a medical student. He should decide on the diplomas he requires, and guide his studies accordingly. Most of the schools now have a composition fee, entitling to all required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to perpetual attendance on all lectures and hospital practice. It is better to take out the perpetual ticket, as all contingencies are thereby provided for. The fees are mostly payable in two or three instalments, at the commencement of each Winter Session. The Dean will always forward details, as well as any special information of which a student may find himself in need. The first instalment varies from forty to fifty guineas; the second is a like sum; the third usually only makes the whole paid a hundred guineas or a little over.

The student who comes from the country to enter in London not unfrequently requires lodgings. Those who can live with relatives and friends are, of course, best suited; but not a few find themselves very comfortable in furnished apartments, which are to be had in respectable streets near all the hospitals. Two brothers or two friends

can, of course, do this a little less expensively than one. We have known a good sitting-room and bed-room hired for the Session at half a guinea a week. The price varies with the season a little, and some can afford more than others, and therefore can always have a selection of better rooms.

Residence settled, student life begins on the 1st of October, by hearing the Introductory Lecture, at the conclusion of which the fees may be paid, unless they have already been handed over.

It should be mentioned that one or two of the medical schools have collegiate institutions in connection with them where rooms may be had instead of the more usual plan of taking lodgings. Some of the lecturers at most schools receive pupils, and all of them will at any time afford special information to those who may inquire of them. It is therefore a good plan to communicate with any one of them with whom the intending pupil or his parents may have any acquaintance, or to whom an introduction can be obtained. Or, in any case, the Dean will at once reply to inquiries by post and forward a full prospectus.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with knowledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. We never competed for them, nor encouraged others; and some of the most eminent men hold the same views. Others, however, differ from us, and the pupil may judge for himself. Competition for appointments to dresserships and other offices, where much practice is seen, stand on a different footing. No prize can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others, the diligent gain them without extra expense. The student, having selected his hospital and school, has chosen his teachers. We have only to remind him that however able they may be, the result depends on his own application. Let him supplement their efforts by giving all his energy to the pursuit of knowledge, and there is not one of our schools of medicine in which he will not acquire such a knowledge of his profession, that when the time comes he will pass his examinations with ease, and, what is more important still, will then be able to practise in our noble profession with benefit to the sick to whom he may minister.

The Regulations of the Licensing Bodies and of the Schools of Medicine.

THE information most important to students may be divided into two parts—first, the regulations with which they must comply before they can present themselves for examination to any of the Licensing Bodies; second, the means that exist to enable them to do so. In the first category are to be placed the regulations of the Corporations; in the second, some account of the many Schools of Medicine and Hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they

have obtained their diplomas, especially in the Public Services. Hence we furnish some particulars that will be interesting to those who contemplate entering the Army or Navy, or taking service under the Poor-law Board.

According to this plan, we proceed to consider, first of all, the regulations of the Qualifying Bodies.

THE UNIVERSITIES.

OXFORD AND CAMBRIDGE.

THE elder English Universities have of late years opened their doors much wider than heretofore, and that without losing any of the prestige they possessed. Those who propose to follow their course of education need not any longer enter at any particular College or Hall, although it will probably be long before lodger students will be very numerous. There are advantages in the College life that will not be willingly given up by those who can afford it, and, for a purely medical career, it would be perhaps preferable for those who would not like to enter a College to graduate at the London University.

We would here urge upon every student who may enter any University the great advantages they would derive from a course of study in the Faculty of Arts, and we strongly advise every one who has the time to take a Degree in Arts before commencing his medical curriculum. A Degree in Arts stamps a man for life; and as some examination must be passed before the commencement of professional study, it would always be best to take such a degree. A University Degree in Arts is recognized universally as the preliminary examination, and possesses its own value, besides exempting from other tests.

UNIVERSITY OF LONDON.

THE medical degrees of this University have now obtained a reputation second to none, and no student can therefore propose to himself a higher qualification. The training is rather longer than that required for the diplomas of most of the corporations. The examinations are very stringent, and it is in after years that the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is, therefore, very desirable he should matriculate before entering a medical school, otherwise two years will be lost. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree. The medical degrees of the University are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees of Bachelor and Doctor of Science are also now obtainable. There are, at each stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly prized distinctions in various branches. There are also scholarships for the most successful.

UNIVERSITY OF DURHAM.

THE degrees of Bachelor and Doctor of Medicine are granted by this University, as is also the degree of Master of Surgery. There is also a licence in medicine, to obtain which residence is not essential. A licentiate cannot pass to the M.B. until he has obtained the degree of B.A., or passed an equivalent examination. Only M.B.'s of 21 terms' standing can proceed to M.D.

There is a medical scholarship of £25 tenable for four years, and the fees, both Collegiate and University, are very moderate.

THE CORPORATIONS.

FROM the Universities we pass to the other bodies that can give authority to practise.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

THE FELLOWSHIP.

THE Fellowship is only attainable by election. No one can be proposed who is not a Member of four years' standing. The mode of election has long given much dissatisfaction, as the readers of THE MEDICAL PRESS AND CIRCULAR are well aware, from the numerous articles and communications that last year appeared. There is a general admission as to the justice of our strictures, and from the liberal feeling of a large body of the Fellows, it is not improbable that a reform already initiated may bear good fruit.

THE MEMBERSHIP.

A person may become a Member of this College without holding a degree in Medicine, or indeed any other diploma. This is not very often done; for the Membership gives no right to the use of the title doctor, though some Members not possessed of a degree do so style themselves. This is, however, in direct violation of the rules of the College to which a Member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any British University are admitted to an examination for the Membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even foreign graduates of accredited Universities have no difficulty in being admitted to examination. During the so-called year of grace this diploma was given to any M.D., on payment of ten guineas; but such a wrong is not likely again to be perpetrated.

THE LICENCE.

This diploma authorizes the holder to practise his Profession as a Licentiate of the College. Unless a graduate of some University, he is forbidden to use the title of doctor, but we regret to say many do so. At first it was regarded as a medical diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments. It has been proposed to give this licence to Licentiates of the Apothecaries' Company, on payment of a fee, *without examination*. Such a course might bring a little money to the College, but could confer no credit on any one. Those who hold the Company's licence have their legal right to practise, and have already made their position. To confer the College licence for cash would degrade it in the estimation of all who have obtained it by examination. The College has done its share of trafficking in diplomas, and we trust will not load itself with another year of (dis-)grace.

During the past year we have had to record the most important change that has ever occurred in reference to the qualifications of general practitioners. This licence of the London College of Physicians has been recognized by the Poor-law Board as a qualification in surgery as well as medicine. Consequently, this single diploma is sufficient to enable any one to take a Poor-law appointment. It ought, therefore, to become a single authority to practise every department of the Profession. In such case, any one contented with the diploma of L.R.C.P. Lond., would have all he needed, and the one faculty system so long desired by earnest reformers would be established.

It is to be supposed that the College will follow up its advantage, and protect all its Licentiates in the exercise of all branches of the Art of Healing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No Corporation has exercised so great an influence over the Profession in England as this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. In a parish appointment, its membership, though no longer essential, carries great weight. Hence, most English students intend to prepare themselves for this, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College has two grades, Member and Fellow. It also gives a diploma in midwifery, but this is mostly confined to those who are already Members.

THE FELLOWSHIP.

Members of long standing can be admitted by election. As, however, this grade is also obtainable by examination, this is the more usual mode. Consulting surgeons mostly take the Fellowship by examination, though there are many hospital surgeons in London who have contented themselves to remain Members.

A Member of the College of eight years' standing is admitted to examination on the production of a certificate of three Fellows, that he has been engaged for eight years in the practice of surgery, and is a fit and proper person to be admitted a Fellow.

THE MEMBERSHIP.

This diploma gives no vote in the affairs of the College. It is in effect only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the practice of medicine, and also in the practical employment of splints, bandages, and other surgical appliances.

APOTHECARIES' SOCIETY OF LONDON.

THE Licence of the Worshipful Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognized by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications, of the value of which they are ignorant. The drawback to many a student is that, constrained by the Act of Parliament, the Society requires apprenticeship. This clause has, however, received a very liberal interpretation, and every pupil of a licentiate, who is certified to have served *after the manner* of an apprentice, is considered to have fulfilled the requirement. During this term he may also have carried on his hospital studies. Everyone, therefore, who can show this certificate, intending to settle *in England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society; and as the fee is only six guineas, a very large number of young men will, we doubt not, secure this possible avenue to appointments.

Every candidate for a certificate of qualification to practise as an Apothecary must produce testimonials—

1. Of having passed in general education.
2. Of apprenticeship of five years to a practitioner qualified by the Act of 1815. This period may include the time spent at lectures and hospital.
3. Of being of the age of twenty-one.
4. Of good moral conduct.
5. And of the required course of study.

Irish Hospitals and Schools of Medicine.

SCHOOL OF PHYSIC, UNIVERSITY OF DUBLIN.

THIS School was established by Act of Parliament 40 George III., and is under the joint government of the Board of Trinity College and the King and Queen's College of Physicians.

Institutes of Medicine, Professor Law. Materia Medica and Pharmacy, Professor A. Smith. Surgery, Professor R. Smith. Anatomy and Chirurgery, Professor MacDowel.

Its Medical School is at Trinity College, where a spacious dissecting-room has recently been erected. Information as to the Medical Scholarships and Exhibitions in this School will be found amongst the regulations of the University of Dublin.

For further particulars see advertisement.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

THIS School is under the superintendence of the Council of the College, who appoint the professors. The Introductory Address will be given on the first Monday in November. The Professor of Physiology will commence his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting-rooms have been recently much enlarged. Arrangements have been made to give increased facilities for instruction in Operative Surgery and Chemical Analysis. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the Winter Session. The Junior Surgical Society meets fortnightly in the school, and several prizes have been offered for the best essays read during the Session.

For further particulars see advertisement.

THE LEDWICH SCHOOL OF MEDICINE, PETER STREET.

THIS School, claiming priority of foundation before any of its kindred unchartered institutions were projected, was established in 1810 by J. Kirby, and has, since then, under the energetic administration of the Messrs. Ledwich and Dr. Mason, maintained a very high prestige as an educational institution. It is situated next door to the Adelaide Hospital in Peter-street, about five minutes' walk from the Meath Hospital, Royal College of Surgeons, and Mercer's Hospital, and the Coombe Lying-in Hospital, and ten minutes from the Catholic University School, the University, and the City of Dublin Hospital. The hospital in most immediate connexion with it is Mercer's.

For further particulars see advertisement.

STEEVENS' HOSPITAL SCHOOL.

THIS hospital is conducted on the plan of the London Hospital Schools, combining, in one establishment, all the departments of medical education. Situated in the centre of a district occupied by some of the largest manufacturing concerns, its beds are constantly filled with accidents of a serious nature. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane, Dr. Croker, consulting physician, being one of the medical attendants. All morbid specimens are most carefully examined and preserved by the curator, who is an officer regularly appointed and paid by the Board of Governors.

There is accommodation for residence of seven surgical and four medical residents; besides whom the Resident-Surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer six months; including hospital ticket; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

PRIZES.

3 Cusack Medal and Exhibition, of £3, £5, £3; 2 Midwifery Assistants, £30 each; 1 Medical Clinical Prize, £10 10s.; 1 Surgical Prize, £10 10s.

The session opens with distribution of prizes in the first week in November.

For further particulars see advertisement.

THE CARMICHAEL SCHOOL OF MEDICINE.

THE various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the proprietors. As the building was designed with special reference to the requirements of a large medical class, every convenience is afforded to the student in the prosecution of his studies.

The proximity of this School with the House of Industry Hospitals, and its connection with these institutions as well as with the Mater Misericordiarum, Meath, and Jervis-street Hospitals, through its teachers, ensures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which will henceforth enable the proprietors to distribute prizes to the amount of £60 yearly; and the Scholarship, value £15 yearly, which the friends of the late Dr. Mayne have founded in his name, will be allotted at the termination of the Winter Session.

For further particulars see advertisement.

THE MEDICAL SCHOOL OF THE CATHOLIC UNIVERSITY

OCCUPIES a central position, and is within a short distance of the principal hospitals of the city; it possesses a complete laboratory for the study of practical and experimental chemistry; the dissecting room is lighted with gas for the convenience of industrious students; there are class rooms for private tuition on the premises, likewise a reading-room, and a college for the residence of medical students has been specially provided, containing a library of the most approved class-books. Two exhibitions, each of the value of £20, are offered for competition in the ensuing year—viz., one in the combined subjects of chemistry, physiology, microscopic anatomy, and botany; and one in surgery, medicine, and midwifery. A gold medal of the value of £7 is likewise offered in materia medica, medical jurisprudence, and practical chemistry, in the ensuing summer session. The students of the physiological and botanical classes are instructed in the use of the microscope, and how to recognize the various animal and vegetable tissues, and fluids.

There is accommodation for residence of students in connection with the institution, which will accommodate at least forty students.

The fees payable for the privilege of residence are from £7 to £10 the academic year.

The arrangements and cost of maintenance are by a club, voluntarily constituted, and the officers of which are annually elected by the students.

The term of residence is nine months.

Prizes and Exhibitions.—Two exhibitions of £20 each, and one gold medal of the value of £7, besides two class prizes in each class of the respective value of £3 and £2, for which the examination takes place in the first week in April and the first week of July.

For further particulars see advertisement.

THE CITY OF DUBLIN HOSPITAL.

THIS hospital is situated in Upper Baggot street, about ten minutes' walk from the Royal College of Surgeons and the Medical School of Trinity College, and twelve from the Ledwich Schools and the School of the Catholic University. Physicians, surgeons, and assistant physicians are, with three exceptions, either Professors or Demonstrators in the School of the Royal College of Surgeons in Ireland. The hospital contains 104 beds, and accommodates about 800 intern patients annually. There are special wards for ophthalmic diseases, on which subject a special course of lectures is delivered by Dr. Jacob, and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of £20 per annum (with apartments) is obtainable by competitive examinations by all students, and a special certificate is granted. The fees for hospital attendance are—nine months, £8 8s.; six months, £6 6s.; summer three months, £3 3s. Perpetual, £21.

A special course of lectures on ophthalmic surgery is now required for the surgical qualifications of the University of Dublin.

For further particulars see advertisement.

THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

THIS hospital is situated about a quarter of an hour's walk from the University, and within a few minutes of the College of Surgeons and the Ledwich Schools of Medicine; affords every facility for the treatment and study of disease. Its salubrious position and long-established character call for constant admission to its accident, chronic, fever, surgical, and children's wards, which are thus constantly occupied with cases illustrative of medicine and surgery.

Four prizes will be given at the termination of the winter course to the best answerers in their respective classes.

The office of resident pupil is open to pupils as well as apprentices.

For further particulars see advertisement.

ST. VINCENT'S HOSPITAL.

THIS hospital was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. Dr. O'Ferrall was the original medical officer. The ward for "*Enfants Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established two years since at Stillorgan, the greatest benefit in the way of rapid recoveries and convalescence after acute attacks has followed. These institutions are wholly supported by voluntary contributions. The clinical instruction in medicine and surgery is given by Dr. O'Ferrall, Dr. Quinlan, Dr. Mapother, Mr. O'Leary, and Dr. Cryan. Prizes are awarded at the end of the winter session.

For further particulars see advertisement.

THE ADELAIDE HOSPITAL

Is in Peter-street, next door to the Ledwich School. From the 1st of October, the physicians and surgeons will visit the wards, and give instruction at the bed-side, at the advertised hours, and the course of clinical lectures will be commenced in the beginning of November.

For further particulars see advertisement.

SIR PATRICK DUN'S HOSPITAL,

FOUNDED on the endowment of Sir P. Dun, and for many years receiving nothing but purely medical cases, has been lately reconstituted as a Medico-Chirurgical Hospital. It is in immediate connection with the School of Physic, and its physicians and surgeons are all professors in that School. The University requires nine months' attendance at this hospital from candidates for the M.B.

Hospital fee for twelve months, including nine months' clinical lectures, nine guineas.

For further particulars see advertisement.

THE MATER MISERICORDIÆ HOSPITAL,

SITUATED in Eccles-street, is a new and handsome building, and, when it is completed, will be one of the finest charitable institutions in Dublin.

FEES.—Nine months, *Sl. 8s.*; six months, *6l. 6s.*; three months, *3l. 3s.*

For further particulars see advertisement.

MERCER'S HOSPITAL

Is situated within a few minutes' walk of the Royal College of Surgeons, Ledwich School, Trinity College, and Catholic University School.

Two new wards for the reception of fever and contagious diseases are now open, in addition to the previous accommodation of the hospital.

Terms of Attendance.—Six months, six guineas; nine months, eight guineas; perpetual pupils, 21*l.*

For further particulars see advertisement.

JERVIS-STREET HOSPITAL.

THIS hospital is situated in the neighbourhood of the Carmichael and Catholic University Schools, and in a part of the city not otherwise provided with hospital relief.

For further particulars see advertisement.

ROTUNDO LYING-IN HOSPITAL.

THIS well-known institution is the largest and oldest maternity hospital in the United Kingdom, and the repute in which it is held attracts students from all parts of the world. It accommodates an average of 1,700 intern patients, including those admitted to the chronic wards labouring under the various forms of uterine complaints, and is under the care of the Master, who is elected every seven years, and two assistants, who hold these appointments for three years. The mastership is at present held by Dr. Johnston, and the assistants are Dr. J. Guinness Beatty and Dr. Thomas More Madden. There is, in addition, an external maternity department, where patients, procuring a ticket properly signed, can be attended at their own homes; also, a dispensary is held every morning for diseases of women and children. Clinical instruction is given each morning both in the labour as well as in the chronic wards, and two courses of lectures are delivered in the year, which are recognized by all the licensing bodies.

A student entering for the practice of the hospital pays a fee of 10*l.* 10*s.* for six months. During that time he is required to attend at least thirty cases, either within the walls of the hospital or at the residence of patients who may apply for assistance. For this course of study, on examination, a diploma is given, which is received as a qualification in midwifery in the public services.

A limited number of students is admitted to reside in the hospital, for which they pay a fee of 20 guineas for six months.

COOMBE LYING-IN HOSPITAL.

THIS hospital was founded in 1826, but it was not till 1867 that it was incorporated by Royal Charter, which enables its medical officers to issue diplomas qualifying the holders to practise midwifery. By a clause in the charter the diplomas issued antecedent to its date have been made of equal force and value with those issued subsequent thereto. This hospital divides with the Rotundo almost the entire of the obstetric hospital practice of Dublin. It is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females, gives admission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as masters, and Dr. Roe, as assistant master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is 4*l.* 4*s.* for six months as extern, and 10*l.* 10*s.* as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases that may be admitted to the labour wards, or may call for his assistance outside. In difficult cases he has the superintendence of the resident medical officer, and of the masters when necessary. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident pupil midwifery assistantships are obtainable annually by competitive examination, for which all pupils who have obtained their midwifery diploma are eligible.

For further particulars see advertisement.

ROYAL COLLEGE OF SCIENCE FOR IRELAND,
STEPHEN'S GREEN, DUBLIN.

THIS College supplies, as far as practicable, a complete course of instruction applicable to the Industrial Arts. The subjects of instruction are: Pure and Applied Mathematics, Descriptive Geometry and Mechanical Drawing, Mechanism, Theoretical and Applied Chemistry, Chemical Analysis, Physics, Botany, Zoology, Geology and Palæontology, Mineralogy, Mining, Machinery, Surveying, Agriculture. The course of instruction extends over three years, but students may enter for any of the courses, and they receive certificates after examination. The College course qualifies for appointments in the Engineering Department for India.

There are four Royal Scholarships of 50*l.* yearly each, with free education, tenable for two years.

The Session commences on Monday, October 4th.

Provincial Colleges of Ireland.

QUEEN'S COLLEGE, BELFAST.

THE first Matriculation Examination will commence on the 22nd October. There will be additional Matriculation Examinations on the 14th November for those who have not been able to present themselves at the first. Lectures will commence on 1st November. No student can be permitted to enter after the 14th November. Two junior scholarships, value £25 each, are awarded to matriculated students commencing the first year of their study. The examination for these will take place immediately after the first Matriculation Examination. Two of similar value to students of the second year, two to students of the third year, and two to students of the fourth year.

For subjects of examination and other information see Queen's College Calendar for 1865. At the termination of the session prizes will be awarded for proficiency in the several classes.

The trustees of the "Charters' Educational Fund" grant annually, for ten years, a sum of £50, for the purpose of establishing an exhibition in connection with the Belfast School of Medicine. The competitive examination for this exhibition will be held at the end of the session, at which all medical students can compete.

FEES.—Practical chemistry, 3*l.* Anatomy and physiology, first course, 3*l.*; subsequent course, 2*l.* Anatomical demonstrations and practical anatomy, each course, 3*l.*; for subjects each session, 15*s.* Other medical lectures, first course, 2*l.*; each subsequent course, 1*l.*

BELFAST GENERAL DISPENSARY.

THIS institution is the only hospital for the reception of injuries and surgical diseases in Belfast, and contains 150 beds.

For further particulars see advertisement.

QUEEN'S COLLEGE, CORK.

MEDICAL SCHOLARSHIPS.

FIRST YEAR.—One to the candidate who shall have most distinguished himself at the examination for science scholarships of the first year in Arts, and one to the candidate who shall have most distinguished himself at the examination for literary scholarships of the first year in Arts. Candidates for these scholarships shall have previously declared themselves, and have matriculated as medical students.

Subjects for the second year—Anatomy and physiology, chemistry, general physics, zoology and botany, the French language.

Subjects for third year—Anatomy and physiology, practical anatomy, materia medica, practical chemistry.

Subjects for fourth year—Anatomy and physiology, practical anatomy, therapeutics, pathology and morbid anatomy, surgery, midwifery.

The fees, whether matriculated or non-matriculated, for attendance on lectures, are 1*l.* for each course, when attended for the first time, and 1*l.* for each re-attendance on the same; except that the fee for anatomy and physiology shall be 3*l.* when attended for the first time, and 2*l.* for every subsequent attendance; and that for practical anatomy or practical chemistry shall be 3*l.* for each attendance.

For further particulars see advertisement.

QUEEN'S COLLEGE, GALWAY.

FACULTY OF MEDICINE.

The College Session.

THE College Session is divided into three terms. The first term commences October 22nd.

Matriculation.

The Matriculation Examination is held at the commencement of the first term; but additional examinations are held before the close of the term. The last Matriculation Examination is held on the 15th November. Each candidate before being admitted to examination must pay a fee of ten shillings, which will be returned to such as fail to pass.

Attendance on Lectures.

All students shall pay the College fee, and a moiety of their class fees, and enter their names with the Registrar, before they are admitted to the classes of the several Professors. No student shall have his name replaced on the rolls at the second term who has not paid the second moiety of his class fees. No student shall be regarded as having kept a course of lectures who has not attended two-thirds of the entire number.

Examinations.

A Sessional Examination is held at the close of each session in the subjects of lectures. There is also a Supplementary Examination on the same subjects at the commencement of the following session.

Scholarships.

Eight junior scholarships, of the value of 25*l.* each, are awarded to students pursuing the course for the degree of M.D. The examinations for junior scholarships are held at the commencement of the first term. Junior scholars are exempted from one moiety of the class fees. The College is empowered to award exhibitions, varying in value from 10*l.* to 18*l.*, at the same examinations as the scholarships, and to be held upon the same terms.

For further particulars see advertisement.

Regulations and Bye-Laws of Licensing Bodies in Ireland.

UNIVERSITY OF DUBLIN.

THE following Degrees and Licences in Medicine and Surgery are granted by the University of Dublin:—

1. Bachelor in Medicine.
2. Doctor in Medicine.
3. Master in Surgery.
4. Licentiate in Medicine.
5. Licentiate in Surgery.

Matriculation.

Every student must be matriculated by the senior lecturer, for which a fee of five shillings is payable; but he need not have his name on the College books, or attend any of the academical duties, unless he desire to obtain a Licence or Degree in Medicine or Surgery. No student can be admitted for the Winter Courses after the 25th of November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the degrees at the same commencements as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures:—

Winter Courses.—Anatomy and Physiology—Practical Anatomy with Dissections—Surgery—Chemistry—Practice of Medicine—Midwifery.

Summer Courses.—Botany—Materia Medica and Pharmacy—Institutes of Medicine—Medical Jurisprudence.

Hospital attendance on Sir Patrick Dun's during nine months, with three consecutive courses of clinical lectures. Also nine months' additional attendance on a recognized hospital, and Practical Midwifery.

Any of the courses may be attended at any recognized medical school, and three of them at Edinburgh University, provided the candidates have kept an *Annus Medicus* in the School of Physic.

The schools recognized are—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Steevens' Hospital. 4. The Ledwich School. 5. The Cecilia-street School.

An *Annus Medicus* may be kept in three ways—1. By attending two winter courses. 2. Or one winter and two summer courses. 3. By nine months' attendance on Sir Patrick Dun's Hospital and Clinical Lectures: together with one winter course or two summer courses of three months' duration.

The fee for nine months' attendance at Sir Patrick Dun's Hospital is twelve guineas.

The fee for the *Liccat ad Examinandum* is £5.

The fee for the degree of M. B. is £11.

Doctor in Medicine.

A doctor in medicine must be M. B. of at least three years' standing, and requires no other qualification.

Total fees for this degree, £13.

Master in Surgery.

This degree can only be obtained by Bachelors of Arts. The curriculum is the same as that for the Licentiate in Surgery, as given below.

Candidates will also be required to perform surgical operations on the dead subject.

Total amount of fees for the degree of Ch. M., £16.

Licentiate in Medicine.

Candidates for the licence in Medicine and Surgery must be matriculated in Medicine, and must have completed four years in medical studies, and must pass an examination in Arts, including Greek, Latin, English, and Mathematics, unless they be students in the Senior Freshman, or some higher class. The medical course necessary for a Licence in Medicine is the same as for the degree of M. B. A fee of £5 is charged on taking the Licence. Licentiates in Surgery of the Royal Colleges of Surgeons, on passing the Art examination, will be admitted to examination for the Licence in Medicine. Such candidates will be exempted from examination in Anatomy and Surgery: Fee for the *Liccat ad Examinandum*, £5. Fee for the Licence in Medicine, £5.

Licentiate in Surgery.

Candidates must have kept one full year in Arts, and will be required to perform surgical operations on the dead subject. The curriculum extends over four years, and is as follows:—Two courses each of Anatomy and Physiology, and Theory and Practice of Surgery; three courses of Demonstrations and Dissections; and one course each of Practice of Medicine, Chemistry, Materia Medica, Midwifery, Laboratory Chemistry, Botany, and Medical Jurisprudence. Also attendance for three Sessions, each of nine months, on a recognized hospital. Of the courses of lectures, which are of six months' duration, not more than three can be attended during any one session. Any of the above-named courses may be attended at any of the medical schools of Dublin, provided the candidate has kept an *Annus Medicus*. A fee of £5 is charged for the licence, and £5 for the *Liccat*.

SESSIONAL EXAMINATIONS.

Candidates for degrees and licences will be subjected to two examinations, one of them preliminary, which will be held at the close of the second year, and the other, after the full curriculum has been completed. The subjects of the preliminary examination are the following: Descriptive Anatomy, Botany, and Materia Medica, Pharmacy, Chemistry, theoretical and practical, with Chemical Physics. The best answers at the preliminary examination will be elected to the scholarships, provided they are in the Senior Freshman, or some higher class, and have kept one *Annus Medicus*.

PRIVILEGES OF MEDICAL STUDENTS.

Medical students, being junior or senior sophisters, and in attendance on the full courses necessary for an *Annus Medicus*, are exempted from the classics of the junior sophister year, and from one of the three optional courses (Mathematical Physics, Experimental Physics, or Classics) of the senior sophister year. To obtain this privilege the student must be matriculated, and the certificate of his attendance on lectures be submitted to the senior lecturer.

FREE COURSES.

Students in Arts having their names on the College-books will be permitted to attend one course free of expense with the Professor of Botany, and to attend the lectures of the University Professors at half price.

MEDICAL SCHOLARSHIPS.

Two medical scholarships are given annually, value 20*l.* per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy, Physiology, Chemistry, Materia Medica, and Botany.

Medical School Exhibitions.

The professors of the University school give three exhibitions annually: two senior, value 15*l.* and 10*l.*, open to all students who have been three years attending the school. The subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine.

One junior, value 15*l.*—the time and subjects of examination being the same as those for the medical scholarships.

Expense of obtaining the degrees of Bachelor in Medicine and Master in Surgery in the University of Dublin:—Lectures, 49*l.* 7*s.*; Hospitals, 28*l.* 7*s.*; Degree Fees, 32*l.* = 109*l.* 14*s.*; Private Tuition, say, 20*l.*; Total, 129*l.* 14*s.*

N. B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to 83*l.* 4*s.*, should be added to the foregoing, making the total cost something over 200*l.*

The Board of Trinity College have recently passed orders:—

1. That three-fourths of the courses of lectures must be in all cases attended.
2. That the system of perpetual pupils be abolished.
3. That a daily roll be called by each Professor.
4. Students in Arts shall be entitled to attend one course in Botany, and to receive a certificate free of charge.
5. Candidates for degrees and licences in Surgery shall be required to attend one course only on Anatomy, for which he shall be charged three guineas.
6. The two courses delivered by the Professor of Surgery shall include practical instruction in Operative Surgery on the dead subject; and for each the professor shall charge four guineas.
7. The Professor shall charge three guineas for the winter lecture in Chemistry.
8. Laboratory instruction shall be substituted for the second course of chemistry, hitherto delivered, for which the Professor of Chemistry shall charge five guineas.
9. Students in Arts may attend the Professors of Surgery and Chemistry, and to receive certificates on payment of half the fees.
10. That after Shrovetide, 1868, all candidates in Medicine shall produce certificates in practical Midwifery, including at least six deliveries.

See advertisements of School of Physic and Sir Patrick Dun's Hospital.

THE QUEEN'S UNIVERSITY IN IRELAND.

FACULTY OF MEDICINE.

DEGREE OF DOCTOR OF MEDICINE.

EACH candidate for the degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts, and to have been Matriculated in Medicine.
2. To have attended in one of the Queen's Colleges, Lectures on one Continental language for six months, and on Natural Philosophy for six months.
3. To have attended, in some one of the Queen's Colleges, two other courses of the medical curriculum. For the remainder of the courses, certificates will be received from the Lecturers in Schools, recognized by the Senate.
4. To pass two University Examinations—the First University Examination and the Degree Examination.

The curriculum of Medical study extends over four years, and is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, and Materia Medica. Practical Chemistry in a recognized Laboratory is also to be attended during the first period, and the practice during six months of a Medico-Chirurgical Hospital, containing at least sixty beds, together with the Clinical Lectures delivered therein.

The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. During this period Students attended Practical Midwifery, and eighteen months' practice of a Medico-Chirurgical Hospital, containing at least sixty beds, and in which clinical instruction is delivered.

At least two of the above courses of Lectures must be attended in some one of the Queen's Colleges; the remainder may be taken at the option of the candidate, in any University, College, or School recognized by the Senate of the Queen's University.

The University Examinations are held twice in each year, in June and September.

The June Examinations are Pass Examinations, and commence on the Tuesday following the second Saturday in June.

The Honour Examinations commence on the last Tuesday in September, and are followed by Pass Examinations.

Each candidate for examination in June must forward to the Secretary, before the 1st of June, notice of his intention to offer himself, along with his certificates; and each candidate for examination in September or October must forward similar notice, along with his certificates, before the 1st of September.

THE FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The First Examination may be passed either in June or September.

Students may present themselves for this Examination at the termination of the first period of the Curriculum, or at any subsequent period.

Before being examined, each Candidate must produce evidence of having completed the course recommended for study during the first period.

The First University Examination comprises the subjects recommended for study during the first period, along with which any Candidate may present himself for Examination in Experimental Physics and Modern Languages, if he has attended in one of the Queen's Colleges the courses on these subjects.

English Composition forms a part of all University Examinations.

HONOURS.

Competitors for Honours will be examined in all the subjects of the First Medical Examination, including Experimental Physics and Modern Languages.

Two Exhibitions, one consisting of two instalments of 20*l.* each, the other of two instalments of 15*l.* each, are awarded under certain conditions at this examination.

The candidates who pass with Honours will be arranged in three classes.

Candidates who defer passing their First Medical Examination until they present themselves at the degree examination are not eligible for Honours with the First Examination.

Honour and Pass Examinations are held in September. The Examination held in June is a Pass Examination.

DEGREE EXAMINATIONS IN MEDICINE.

Examinations for the M.D. will be held in June and September. The fee is 5*l.*

Each candidate must produce—

1. A certificate from the Secretary of the Queen's University, that he has passed the previous examination, unless he presents himself for both examinations simultaneously.
2. From the Council of his College that he has passed a full examination for Matriculation in Arts, and has been admitted a Matriculated Student in the Faculty of Medicine.
3. That he has attended in the College lectures on one Modern Language, on Experimental Physics, and two other courses.

4. That he has completed all other prescribed courses.

The Degree Examination comprises the subjects recommended for study during the second period, along with Experimental Physics and one Modern Language, unless an Examination in these subjects have been already passed at the previous Medical Examination.

The Examination for the Degree of M.Ch. comprises in addition an examination in Operative Surgery.

Candidates who graduated with Honours will be arranged in three classes. Candidates who take a first class will receive a medal and prize. Candidates who take a second class will receive a prize. Candidates who take a third class will receive a certificate of honour.

The examination for the Degree with Honours will commence on the last Tuesday in September, and will be followed by the examination of those candidates who seek to graduate without honours.

See advertisements of Queen's Colleges, Belfast and Cork.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Royal College of Surgeons is the principal Surgical Licensing Corporation of Ireland, and confers the great majority of the surgical qualifications granted in that division of the United Kingdom. Although there is a medical school attached to it, the College receives and grants its diplomas on certificates from all medical schools of standing. The letters testimonial confer the title of licentiate, with full qualification to practise; but the exercise of the privileges of attending and voting as a member of the College is reserved for Fellows. The Medical School of the College is under the superintendence of the Council, by whom the Professors are elected. Important modifications have been recently made in the system of examination, quarterly sessions of the court having been established, and voting by numbers instead of "Yes" and "No" introduced. Full information as to these changes will be found in the appended regulations.

REGISTRATION OF PUPILS.

Every person shall be registered as a pupil on the college books on payment of five guineas.

Registered pupils can study in the museum on two days in each week, and to read in the library every day, from ten to one. They may also attend the Lectures on Comparative Anatomy, and obtain the certificate without payment. No student is admitted to the sessional or final examination for letters testimonial until he becomes a registered pupil.

CLASSICAL EXAMINATION.

Registered pupils are admitted to examination at any period previous to the final examination for letters testimonial.

Students not registered pupils are also admitted upon payment of ten shillings; but they are not enrolled as registered pupils, until they have paid the five guineas.

The following are the subjects for the Preliminary Examination:—The English Language, including Grammar and Composition. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. Geometry, first two books of Euclid. Latin and Greek, including Translation and Grammar. In Greek—The Gospel of St. John, the Menippus of Lucian, or the First Book of Xenophon's Anabasis. In Latin—The First and Second Books of the *Aeneid* of Virgil, the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are held quarterly, viz. :—On the third Wednesday in January, April, July, and October in each year. Fee, ten shillings.

THE FELLOWSHIP.

Candidates must be twenty-five years of age, have studied six years, and have attended a course on Comparative Anatomy, on Botany, and Natural Philosophy. The fee is thirty guineas for a resident in Dublin, and twenty for a non-resident, having been previously a licentiate.

LETTERS TESTIMONIAL.

Every registered pupil shall be admitted to an examination if he shall have laid before the council—*a.* A receipt showing that he has lodged twenty guineas. *b.* A certificate of an examination in Greek and Latin. *c.* Certificates of four years'

study. *d.* Certificates of three years' hospital attendance.*

e. Certificates of attendance on the following lectures:—

Three Courses.—Anatomy and Physiology; Theory and Practice of Surgery; Dissections with Demonstrations.

Two Courses.—Chemistry (or one on general and one on practical Chemistry).

One Course.—Midwifery; Medical Jurisprudence; Botany; Materia Medica; Practice of Medicine.

DIPLOMA IN MIDWIFERY.

Any Fellow or Licentiate shall be admitted to an examination upon the following documents:—

a. Certificates of one course of lectures on Midwifery and Diseases of Women and Children.

b. That he has attended a recognized lying-in hospital for six months; or a recognized dispensary for lying-in women and children, devoted to this branch of surgery alone.

c. That he has conducted thirty labour cases. Candidates for the Midwifery Diploma shall be examined on the organization of the female; the growth and peculiarities of the foetus; the practice of Midwifery, and the diseases of women and children.

The Candidate pays £1 6s. for the Midwifery Diploma provided he takes it out within one month from the date of his Letters Testimonial; after that date the Fee will be Two Guineas.

REGULATIONS AS TO EXAMINATIONS.

Letters Testimonial.

Five examiners at least are present. Each candidate shall be examined upon Anatomy, Physiology, the Theory and Practice of Medicine and Surgery, Materia Medica and the form of prescription, and shall perform such surgical operations or dissections, or explain such anatomical and pathological preparations as the examiners may require.

Licentiates of a college of physicians or graduates in medicine of a University, shall be examined in general and descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery. Rejected candidates cannot present themselves until after six months. In addition to the oral examinations, candidates are required to give written answers to written questions.

FELLOWSHIP EXAMINATION.

Five examiners at least, together with the president, or vice-president, and two members of the council, shall be present. Each candidate shall be examined on two days. The subjects of the first examination shall be Anatomy and Physiology (human and comparative); those of the second, Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery. In addition to the oral examinations, candidates shall be required to give written answers to written questions. The candidates shall also perform dissection and operations on the dead body. Rejected candidates cannot present themselves until after one year.

ORDER OF QUARTERLY EXAMINATIONS.

1st. Candidates shall return their names to the Registrar, and lodge their fees and certificates one week before examination.

2nd. Candidates shall be examined in alphabetical order.

3rd. The candidates assemble at three o'clock P.M., when twelve, selected according to alphabetical order, will each (for the junior class) receive three written questions on Anatomy and Physiology, and one on Materia Medica, and (for the senior) four written questions on Surgery and Practice of Medicine, which they will be required to answer within one hour; at the end of the hour each candidate shall enclose his questions and answers in an envelope, with his name on the back, and hand same to the examiner superintending.

4th. The seven examiners shall attend on each day at four o'clock, to commence the Oral Examinations, and four of them shall examine for a quarter of an hour, at four separate tables in the junior class—viz., three on Anatomy and Physiology, and one on Materia Medica, and in the senior class, three on

* ATTENDANCE ON PROVINCIAL HOSPITALS.—Candidates who shall have attended recognized Hospitals during three Winters, shall be admitted, if they shall produce certificates of attendance during a like number of months at a County Infirmary, or Provincial Surgical Hospital, containing at least fifty beds, provided the surgeons shall make returns, in the months of May and November of the number of students so attending.

Surgery and Practice of Medicine, and one on the form of prescriptions.

5th. Two councillors shall be summoned to witness the examination of each candidate, and shall accompany him from table to table till his examination be completed, when the voting papers having been examined, and the result declared, the name of each successful candidate shall be enrolled in a book kept for that purpose in the College.

Examinations shall be held on the second Tuesday in February, May, August, and November, at which candidates shall be divided into two classes—junior and senior.

The Junior Class shall produce certificates of three courses of Lectures on Anatomy and Physiology, three courses on Practical Anatomy, with dissections; two courses on Chemistry, one course on Materia Medica, one course on Botany, and one course on Forensic Medicine.

This class shall be examined in Anatomy, Physiology, and Materia Medica.

The fee for this examination shall be five guineas; not to be returned in case of rejection, but to be allowed in the fee for the second examination.

The Senior Class shall produce certificates of three courses on the Theory and Practice of Surgery, one course on the Practice of Medicine, and one course on Midwifery; also of attendance on a recognized hospital for three Winter and three Summer Sessions.

This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of prescription.

Both these examinations shall be partly written and partly oral.

The fee for this examination shall be fifteen guineas.

Fees to be paid by Candidates for Letters Testimonial.

1st. The candidate pays ten shillings for his preliminary examination.

2nd. Five guineas as registered pupil of the College.

3rd. Five guineas for the Junior Class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4th. Fifteen guineas for the Senior Class examination—total, £26 15s.

5th. Every candidate rejected at the quarterly examinations shall be required to pay to the College the sum of two guineas on applying for re-examination.

See advertisement of School in connection with College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RESPECTING THE LICENCES IN MEDICINE AND MIDWIFERY.

CANDIDATES for the Licence in Medicine, who have not previous to presenting themselves obtained some of the qualifications hereafter mentioned, must give proof of having attained the age of twenty-one, of four years' study; and of having studied Anatomy, Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica and Botany, Medical Jurisprudence, Practice of Medicine, Pathology, Surgery, Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months (or for eighteen months, with nine months, at a Medical Hospital), both hospitals not being taken out in the same year.

Of six months' Practical Midwifery at a hospital, or other evidence of having attended Practical Midwifery.

And, if not personally known to a Fellow of the College, must transmit testimonials of character from registered Physicians and Surgeons.

The examination is divided into two parts:—

First Part.—Anatomy, Physiology, Botany, and Chemistry. Second Part.—Materia Medica, Practice of Medicine, Medical Jurisprudence, and Midwifery.

Candidates qualified as follows are required to undergo the second part of the professional Examination only—viz., 1. Graduates in Medicine of a University. 2. Fellows, Members, or Licentiates, of the Colleges of Physicians of London or Edinburgh, admitted upon examination. 3. Graduates or Licentiates in Surgery. 4. Candidates who having completed the curriculum laid down above shall have passed the previous

examination of any of the Licensing Corporations in the United Kingdom.

Under this last regulation gentlemen who have passed the first portion of the examination for the Licence of the Royal College of Surgeons of Ireland or the Royal College of Surgeons of England are exempted from the first part of the examination.

Candidates who have been five years in practice are not required to undergo the written portion of the examination.

Members of the Society of Apothecaries of England or of the Apothecaries' Hall of Ireland are not required to surrender their certificate, but the Licentiates of the College are not allowed to keep open shop for the sale of medicines.

REGULATIONS RESPECTING THE LICENCE IN MIDWIFERY.

Members of the College must undergo a special examination, and shall be distinguished as Practitioners in Midwifery in the Lists of the College.

Candidates not being Licentiates will be admitted on the following qualifications:—The Degree or Licence in Medicine or Surgery, with a Certificate of six months' Lectures on Midwifery, with six months at a recognized Lying-in Hospital, or of having attended Practical Midwifery for six months at a recognized Lying-in Hospital, or other evidence of having attended Practical Midwifery.

FEEES FOR LICENCE AND EXAMINATIONS.

The Fee for the Licence is £15 15s.

The Fee for the Midwifery Diploma is £3 3s.

The Fee for the Licence in Medicine and Diploma in Midwifery, if taken out at the same time, £16.

The Admission Fee, with the exception of £2 2s., is returned to any rejected candidate; and the Admission Fee, with the exception of £1 1s., is returned to any rejected candidate for the Licence in Midwifery: but in the case of a rejected candidate afterwards passing within twelve months, the sum previously deducted is allowed in the fee paid for such second Examination.

The Examinations are held on the *second Wednesday* in every month, except August and September. Gentlemen wishing to present themselves should make application either personally at the College, or by letter addressed to the Registrar at least a *fortnight* previously, when they will receive a Schedule to be filled up.

THE APOTHECARIES' HALL OF IRELAND.

REGULATIONS REGARDING THE LICENCE.

EVERY candidate is required to undergo a preliminary and a professional examination.

THE PRELIMINARY EDUCATION AND EXAMINATION

Include—1. English; 2. Mathematics; 3. French; 4. Latin; 5. Greek; 6. Natural Philosophy; 7. Natural History.

A preliminary examination will be held at the Hall four times in the year—viz., on the third Friday in the months of January, April, July, and October, at two o'clock p.m. This examination will be conducted by printed papers and written answers, and conducted by graduates in Arts of the University of Dublin, with assessors from the Court of the Hall.

Unsuccessful candidates will not be re-admitted to examination until after six months.

Certificates in Arts granted by any of the bodies named in the Medical Act, or by any educational institution approved of by the Medical Council, will be recognized.

THE PROFESSIONAL EDUCATION.

Every candidate for the licence to practise must produce certificates—1. Of having passed an examination in Arts previous to professional study. 2. Of being twenty-one years of age, and of good moral character. 3. Of apprenticeship to a qualified apothecary, or of having been engaged at practical pharmacy with an apothecary for three years subsequent to having passed the examination in Arts. 4. Of having spent four years in professional study. 5. Of having attended the following courses, viz.:—Chemistry, one winter session: Anatomy and Physiology, two winter sessions; Demonstrations and Dissections, two winter sessions; Botany and Natural History, one summer session; Materia

Medica and Therapeutics, one summer session; Practical Chemistry, three months; Principles and Practice of Medicine, one winter session; Midwifery and Diseases of Women and Children, six months; Practical Midwifery at a recognized hospital (attendance upon twenty cases); Surgery, one winter session; Medical Jurisprudence, one summer session; Instruction in the Practice of Vaccination. 6. Of having attended at a recognized hospital the Practice of Medicine and Clinical Lectures during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures, one winter and one summer session. 7. Of having performed vaccination under a recognized vaccinator.

CERTIFICATE OF ASSISTANT.

The Licence Examination is divided into two parts:—First, Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy. Second—Medicine, Surgery, Pathology, Midwifery, Forensic Medicine, and Hygiene. The First Part may be undergone after the second Winter and after the Candidate has attended Courses on the subjects named for this Examination; and the Second after the completion of his studies.

A candidate for the certificate of assistant to an apothecary must have completed at least three years of his apprenticeship, or have a certificate from an apothecary of having been engaged at practical pharmacy for three years, together with a certificate of good moral character.

The examination of the intended assistant will be restricted to the British Pharmacopoeia and to Pharmacy, scientific and practical, including the history and character of medicines, their preparations, combination, and doses, and the translation of Latin prescriptions.

THE PROFESSIONAL EXAMINATION.

The Professional Examinations will be held quarterly, and will commence on the first and second Mondays in the months of January, April, July, and October. They will be carried on as follows:—The First Part, for Junior Students, by papers, on the first Monday, at twelve o'clock, noon; and orally, on the Tuesday and Wednesday succeeding, at the same hour. The Second Part, or Pass Examination for Senior Students, by papers, on the second Monday, at twelve o'clock, noon; and orally, on the Tuesday and Wednesday succeeding, at the same hour.

Candidates who fail to pass the first part of the professional examination will be remitted to their studies for *three months*.

Numerical values will be assigned to the Answers, both written and oral, in the several Examinations, and only candidates who possess a certain proficiency of Medical knowledge in *all* the subjects will obtain "*the licence to practise*."

Unsuccessful candidates at the Pass Examination will not be re-admitted until after the expiration of *six months*.

Doctors of Medicine of any University, or Surgeons of any College of Surgeons, who have served an Apprenticeship, or the required term at *practical Pharmacy*, to a qualified Apothecary, may obtain the Licence by undergoing one day's Examination—the former in Pharmacy and the latter in Medicine and Pharmacy.

Candidates for the Licence must lodge their Testimonials and enrol their names and address with the Clerk at the Hall, in Dublin, a week prior to the day of examination.

See the advertisement in another part of our issue.

Scottish Institutions.

WE now turn to the various bodies in Scotland.

UNIVERSITY OF EDINBURGH.

THIS is a teaching as well as a qualifying body, and the other faculties are as complete as that of medicine. The University confers the degree of M.D., and M.B., as well as that of C.M., and so affords its graduates the opportunity of obtaining, at the same time, a Surgical, in addition to the Medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M., four years of professional study must be completed after passing a preliminary examination recognized by the Medical Council. A degree in Arts in any

British University exempts from the preliminary examination. Of these four years, one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognizes the courses of lectures of extra-academical teachers in Edinburgh, subject to certain regulations. *See advertisement.*

UNIVERSITY OF ST. ANDREW'S.

This University confers the Degree of Master in Surgery (C.M.), as well as the Degrees of Bachelor and Doctor of Medicine. For many years the University did not require residence, and large numbers of medical men resorted to it in order to obtain the Doctorship by examination only. In this the University closely assimilated itself to the University of London, which is exclusively an examining body. The large number of practitioners who obtained the Degree after an examination extending over three or four days, attests the wisdom of a policy which was almost reversed by the University Commissioners. Only ten persons per annum can now obtain the St. Andrew's Degree without residence. There are not a few of the old graduates who look upon this policy as retrograde and illiberal. The University of London maintains its position without requiring academical residence, and no one can doubt that the University of St. Andrew's might have pursued the same course with great success, and by so doing conferred a benefit on the profession. Those who have not now fulfilled their course in a University must either go to the University of London or forego a degree. The London University compels matriculation before commencing Hospital study. Only a relaxation of this rule can secure to all who desire it the opportunity of being examined for a degree.

UNIVERSITY OF ABERDEEN.

This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for medical degrees is the same as that of the University of Edinburgh (which see). Thus four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the Professors in the University.

UNIVERSITY OF GLASGOW.

This is a large teaching as well as examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrew's. The course of study and regulations to be observed by candidates are the same as those of the University of Edinburgh, one year's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of Medicine, together with the three Assessors appointed by the University Court. The fees are:—M.B., 15*l.* 15*s.* (being 5*l.* 5*s.* at each of the three examinations); C.M., 5*l.* 5*s.* (in addition to the fees for M.B.); M.D., 5*l.* 5*s.* (in addition to the fees for M.B.); and 10*l.* 3*s.* for Government stamp. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have fulfilled the prescribed

curriculum may pass the joint examination of this College and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a medical and surgical qualification.

THE FELLOWSHIP.

This is conferred only by election, and no one can be balloted for until he has been a member for one year.

THE MEMBERSHIP

Is conferred on licentiates of a College of Physicians, or graduates of a University, who are 24 years of age and satisfy the College of their knowledge of medical and general science.

THE LICENCE.

The regulations are the same as those for the joint examination. For the Scotch Double Qualification, see next page, with the following exceptions:—Anatomy, Practical Anatomy, and Surgery, six months; Clinical Surgery, three months.

Candidates for the Licence of the College who already possess a qualification from a recognized licensing body, or who have passed the first Professional Examination before a qualifying body, will not be required to be re-examined in Anatomy, Physiology, and Chemistry.

The following are the Fees, payable in all cases in advance:

By a Licentiate, Ten Guineas. By a Member, Thirty Guineas.

When a Licentiate shall be raised to the rank of Member, Twenty Guineas.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE FELLOWSHIP

Is conferred only on persons who have obtained a diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are 25 years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to promise to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

THE LICENCE.

The regulations are the same as those for the Joint Examinations, conducted by the Colleges of Physicians and Surgeons, with the following exceptions: Botany is not required. A second course of Medicine is not required.

The first Professional Examination embraces Anatomy, Physiology, and Chemistry. The second, Surgery and Surgical Anatomy, also Medicine, Midwifery, Materia Medica, Medical Jurisprudence, and Clinical Surgery.

Registered medical practitioners, whose degree or licence in Medicine dates prior to October 1st, 1861, are exempt from the first Professional Examination.

Fee for the diploma, £10.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body has similar powers to those of the Royal College of Surgeons of Edinburgh, and its regulations for Licence and Fellowship are similar. It has also the same arrangement with the Edinburgh College of Physicians for a double diploma. *See advertisement.*

ANDERSON'S UNIVERSITY, GLASGOW.

This is exclusively a teaching body. It offers excellent opportunities for acquiring a complete medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical

knowledge throughout the year. Hospital practice at the Glasgow Royal Infirmary. Every information will be given on application to Dr. McCall Anderson, 1 Woodside crescent, Glasgow, both as to the University, the Hospital, and Diplomas. *See advertisement.*

THE SCOTCH DOUBLE QUALIFICATIONS.

As already stated, the Royal College of Physicians of Edinburgh have made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a medical and a surgical qualification under the Medical Act, thus:—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Coll. of Phys. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be, of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a Board, in which each of the bodies is represented.

It is proper to state that such arrangements as those were contemplated by the Medical Act and authorized by Section XIX., while those under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two professional examinations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council. *See advertisement.*

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

ABSTRACT OF REGULATIONS FOR THE LICENCE.

COURSE OF STUDY.—1. Anatomy, two courses, six months each. 2. Practical anatomy, twelve months. 3. Chemistry, one course, six months. 4. Practical or analytical chemistry, one course, three months. 5. Physiology, not less than fifty lectures. 6. Practice of medicine, one course, six months. 7. Clinical medicine, one course, six months. 8. Principles and practice of surgery, one course, six months. 9. Clinical surgery, one course, six months. 10. In addition to the above courses of surgery and clinical surgery, one six months' course of either of these at the option of the candidate. 11. Materia medica, one course, three months. 12. Midwifery, &c., one course, three months. 13. Medical jurisprudence, one course, three months. 14. Practical midwifery, attendance on at least six cases of labour. 15. Pathological anatomy, three months' instructions in the *post-mortem* room of a recognised hospital. 16. Hospital practice, twenty-four months' attendance on the practice of a public general hospital, containing on the average at least eighty patients.

A certificate of proficiency in vaccination, from a vaccine institution, will be required of every candidate.

Candidates commencing professional study prior to 1st Oct., 1865, are admitted to the final examination after four sessions, of three winter and two summer sessions' attendance at a regular medical school.

Candidates commencing professional study on or subsequent to the above date, must have been engaged in professional study during four years, which shall embrace four winter sessions or three winter and two summer sessions at a medical school.

Candidates are required to be registered in the form prescribed by the General Medical Council at the commencement of their professional study.

Candidates are subjected to two professional examinations; the first embraces anatomy, physiology, and chemistry, and cannot be undergone before the end of the second winter session of study.

The second embraces surgery and surgical anatomy, medicine, midwifery, materia medica, and medical jurisprudence, and cannot be undergone before the termination [of the full period of study.

Intending candidates for the second examination must produce evidence.—1. Of being 21 years of age.—2. Of having passed the first examination.—3. Class and hospital certificates. They will also write out a tabular statement of their whole course of study, for which the secretary, on application, will supply candidates with printed forms.

The fee for the diploma is 10*l.*; 4*l.* payable at the first, and 6*l.* at the second examination.

First examinations will be held on the second Tuesday of each month. Second examinations will take place, the written and clinical parts, on each of the above days, and the oral part on the succeeding day.

Candidates who possess a qualification to practise, are admissible to the second professional examination at the full fee.

In every case of rejection, 2*l.* of the fee is retained, and the remainder is returned.

A candidate may be admitted to examination on a day especially arranged, on paying an extra fee of 3*l.*, which will be forfeited in the event of rejection.

DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain two separate licences; one in medicine and one in surgery.

The "Dr. James Watson Prize," of the annual value of ten guineas, is open to all students who have passed the first examination of the Faculty, and who are not qualified at the date at which the pay is due.

Preliminary Examinations.—22nd October, 5th November, 1869; 29th April, and 22nd July, 1870. **Subjects.**—English, Latin, Arithmetic, Algebra, Geometry, and one of the following, at the option of the candidate, Natural Philosophy, Greek, French, and German.

First Professional Examination for the diploma of the Faculty, on the second Tuesday of every month. **Subjects.**—Anatomy, Physiology, and Chemistry.

Second Professional Examination for the Diploma of the Faculty, on the second Tuesday and Wednesday of each month. **Subjects.**—Surgery and surgical anatomy, medicine, midwifery, materia medica, and medical jurisprudence.

First Professional Examination for the Double Qualification, granted conjointly with the Royal College of Physicians of Edinburgh, on the second Thursday of October, January, April, May, July, and August. **Second Examination** on the same days.

For full particulars see advertisement.

Educational Institutions.

THE Schools of Medicine and the Hospitals to which they are attached next demand attention, inasmuch as at one of them the Student has to go through the curriculum prescribed by the licensing bodies.

In entering a School of Medicine, application is to be made to the Dean. In London the fees range from 80 to 120 guineas for the course of study required for the ordinary diplomas. The sum, if paid at once, is less than if paid in two or three instalments. From 40 to 45 guineas at the commencement of each of the two first years is an ordinary arrangement, the remainder being paid on entering the third winter. The amount of the fees does not differ so much as to make it of importance in the selection of a school.

We now proceed to name some of the characteristics of the most important London Schools.

THE LONDON HOSPITAL.

THIS large hospital is situated at the east end of London, in a district where accidents are of frequent occurrence, and as a field for the study of surgery has always been pre-eminent. It contains upwards of 500 beds; of these 160 are devoted to medical cases, and the remainder to surgery. About 200 are reserved for cases of accidents. The in-

patients number about 5,000 a year; the out-patients, 35,000. Special departments have been organised for diseases of the eye, ear, and skin. Special wards are also set apart for venereal and obstetric cases.

For further particulars see advertisement.

ST. BARTHOLOMEW'S HOSPITAL.

THE great city hospital has always attracted large numbers of students from all parts of the country, so that the school is very flourishing.

H.R.H. the Prince of Wales is the President of the hospital, which receives within its walls upwards of 5,000 in-patients annually, and its out-patients and casualties amount to more than 100,000 annually. It contains 650 beds, of which 403 are allotted to surgical, including ophthalmic, orthopædic, aural, and syphilitic cases, and 247 to medical cases and diseases of women and children. One of the Assistant-Physicians sees the medical out-patients daily, between eleven and two; and one of the Assistant-Surgeons sees the surgical patients daily, between twelve and two.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of 2*l.* 2*s.*, and a further payment of caution money, 3*l.* 3*s.*, is required. The cost of maintenance varies from 30*s.* to 33*s.* per week, payable in each term; and the term of residence is unlimited.

See advertisement.

GUY'S HOSPITAL.

THIS old favourite borough school still attracts as many students as ever. The hospital is, we believe, the largest but one in the metropolis, and from the excellence of its appointments, its situation, and superior staff, it still keeps up its old renown. In special departments, Guy's is the most advanced. This hospital has set the example of giving the appointments to its special departments to gentlemen not on the staff. This liberality has enabled it to secure the leading specialists of the country in its service, and has done more than all the other hospitals together to put down all improper coquetting with specialism.

Guy's is situated close to the London Bridge Railways. Hence, great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, there are many lodgings to be had at a moderate price.

The Resident House Physician is appointed every six months.

House-Surgeons are appointed every four months from those students who have obtained the College diploma.

See advertisement.

ST. THOMAS'S HOSPITAL.

THIS is the borough hospital which was removed for the Charing-cross Railway. The Surrey Hall affords temporary accommodation until the new hospital on the site at Staugate shall have been finished, when, we doubt not, a new impetus will be given to the charity and the school.

There is accommodation for residence and free maintenance in the College-house for the two house-surgeons, resident accoucheurs, one dresser, on obstetric clerk, and assistant obstetric clerk, which appointments are awarded by competition. Very good lodgings are to be obtained at a reasonable rate all round the hospital.

For further particulars see advertisement.

UNIVERSITY COLLEGE AND HOSPITAL.

THIS is situated in a very central position, near the Gower street Station of the Underground Railway, afford-

ing facilities for gentlemen residing in many parts of London. The College gives instruction in every department of knowledge, and specially prepares students for degrees in all the Faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. The Medical Faculty and the Hospital are very complete and flourishing as educational institutions. The University College School specially prepares boys to be ready at a proper age to enter the College.

For further particulars see advertisement.

KING'S COLLEGE.

THIS College gives instruction in all the faculties, and has a Theological Department. It was established by Church of England persons, in opposition to University College, which is a non-sectarian institution, open to all. King's, then, is the Church of England College.

CHARING CROSS HOSPITAL.

THIS hospital, though one of the smaller ones, derives from its situation great advantages. It is in one of the most central positions in London, where there is constant communication with every part. In connection with it the practice of the Royal Western Ophthalmic Hospital, close by, affords an excellent opportunity for the study of that branch of the profession. Other special departments have been established, and the authorities seem to have the courage to establish them on a liberal basis, the hospital staff not monopolising these appointments.

For further particulars see advertisement.

ST. GEORGE'S HOSPITAL.

THE chief advantage of this School is its unrivalled position, at the corner of Hyde Park—perhaps the most salubrious part of the metropolis. Students can easily find lodgings within half an hour's pleasant walk.

A Medical Tutor is appointed to superintend the studies of the pupils, and hold periodical examinations.

On payment of one hundred guineas at entrance, a Pupil becomes perpetual to the Hospital Practice and all the Lectures.

Compounders pay forty guineas on admission, forty guineas for the second year, and ten guineas for each subsequent year, until their payments shall have reached one hundred and ten guineas, when they become perpetual pupils.

Gentlemen may enter separately to Medical or Surgical Practice, or to any single course of Lectures.

The offices of Obstetric Assistant, Curator of the Museum, Medical and Surgical Registrars, and Demonstrator of Anatomy, with salaries of from £50 to £100 attached to each, are held out for competition annually. The William Brown Exhibition of £40 per annum, tenable for three years, is bestowed after a competitive examination. Clinical Prizes are offered annually by Sir Benjamin Brodie and Dr. Acland. Sir Charles Clarke's "Good Conduct" Prize, the Thompson Medal, and the Johnson Memorial Prize are also to be competed for each year. A general examination of all the Students is held at the end of the Summer Session, and Prizes and Certificates of General Proficiency are given to the most deserving.

For further particulars see advertisement.

MIDDLESEX HOSPITAL.

THE hospital contains upwards of 300 beds, of which 185 are for surgical, and 120 for medical cases. There is a special department for cancer cases affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governors' prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the *post-mortem* room. Class prizes are also given,

and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the medical school.

The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and by the Society of Apothecaries is 90*l.*, which may be paid by instalments.

See advertisement.

WESTMINSTER HOSPITAL.

THIS is near the Abbey and the Houses of Parliament, and will be found convenient for all in that neighbourhood. It is well appointed in every respect, and one of the most moderate in respect to fees. The whole course of study for the usual examinations may here be completed for seventy-five guineas, payable in instalments. The perpetual fee is only eighty guineas. Resident appointments, clerkships, and dresserships are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hour's walk from the hospital.

For further particulars see advertisement.

ST. MARY'S HOSPITAL.

THERE is a Medical School in connection with this hospital, which is located at Paddington, in close proximity to the Great Western Terminus. Students with slender purses will find the neighbourhood of the hospital a very moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway to all parts of London. The Clinical Department is very complete. Wards are devoted to the Diseases of Women, including Ovariectomy, and to Ophthalmic Cases. Special study is also provided for in the Out-patient Department for Diseases of the Eye, the Ear, the Skin, and the Throat. Three resident medical officers are appointed for twelve months, and an obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from amongst the students, with a salary of 100*l.* a-year and dispensary fees. These appointments are awarded after competition, without additional fee. For further particulars as to the medical officers, lecturers, and the course of instruction adopted, *see advertisement.*

Provincial English Schools.

THERE are some important Provincial Schools where the medical curriculum may be fulfilled, and which it is necessary to notice.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

THIS School is in connection with the Royal Infirmary, a very large and important institution, containing nearly 300 beds, in which the opportunities for obtaining practical knowledge are very extensive.

PRIZES.

Scholarship, value 42*l.* consisting of a gold medal, value 10*l.* 10*s.* and six months' free board and residence, with dressership and clerkship in the Royal Infirmary. In case the scholarship is gained by a resident pupil, six months' payment (31*l.* 10*s.*) will be returned to him.

Four exhibitions, value 41*l.* 10*s.* each, consisting of free board and residence in the Royal Infirmary for six months, with dressership on award of the Medical Board.

FEES.

For six months' medical and surgical practice, 10*l.* 10*s.* : twelve months, do., do., 12*l.* 12*s.* ; perpetual, 31*l.* 10*s.* . Students are admitted to the practice of the Lock Hospital attached to the Royal Infirmary ; fee, 3*l.* 3*s.* per annum ; six months, 2*l.* 2*s.* . Fee for all the lectures required by the College and Hall, 42*l.*

A prospectus may be obtained from the registrar, Mr. Harrison, 51, Rodney-street.

For further particulars see advertisement.

MANCHESTER ROYAL SCHOOL OF MEDICINE.

SCHOLARSHIPS AND PRIZES.

In addition to three Scholarships, of the value, respectively, of 20*l.*, 15*l.*, and 10*l.* for Perpetual Students, prizes for General Proficiency have been substituted for Class Prizes, in accordance with the suggestions issued by the Royal College of Surgeons. At the end of the Sessions, Certificates of Honour will be awarded for regularity of attendance upon Lectures, and general good conduct.

For further particulars see advertisement.

BRISTOL MEDICAL SCHOOL.

In this town there is ample opportunity of completing a medical education, and the western counties have long availed themselves of the instruction there to be obtained.

The Bristol Medical School educates the students who receive their clinical instruction in either of the two large hospitals of the city—the Bristol General Hospital and the Bristol Royal Infirmary.

Prizes and certificates of honour are given after competitive examinations amongst students of the first, second and third years respectively. The interest of 500*l.* will be given to the prizeman of the third year who shall have been educated at the Infirmary, and can produce certificates of good conduct and moral character. The prizeman of the third year who shall have been educated at the General Hospital will receive, in addition to the school prize, the sum of twenty guineas, given by the committee of that institution.

HOSPITAL PRACTICE.

The General Hospital, founded in 1832, is situated in a populous district near the docks, collieries, manufactories, and railway stations, from which sources the wards are supplied with a great variety of important cases.

The present building was completed and occupied in 1858. It contains 130 beds.

FEES.

Six months, 6*l.* ; one year, 10*l.* ; perpetual, 20*l.* . Library, 1*l.* 1*s.* per annum. Dressership or clinical clerkship, 5*l.* 5*s.* for six months. Two scholarships of 15*l.* each are awarded annually, and a prize of twenty guineas is given to the hospital student who is successful in the third years' competition at the school. Dressers reside in the hospital in weekly rotation free of expense.

BRISTOL ROYAL INFIRMARY.

This infirmary was founded in the year 1735, and is therefore one of the oldest provincial hospitals. It contains 242 beds.

FEES.

Surgeon's pupil, first year, 12*l.* 12*s.* ; two years, 21*l.* ; three years, 26*l.* 5*s.* . Dresser (extra free), one year, 12*l.* 12*s.* ; two years, 21*l.* ; three years, 26*l.* 5*s.* . Physician's pupil, six months, 8*l.* ; one year, 15*l.* ; eighteen months, 20*l.* ; perpetual, 25*l.* . Each pupil is required to pay an entrance fee to the infirmary of 5*l.* and a subscription of 1*l.* 1*s.* per annum to the library, which numbers about 2,700 volumes. The dressers reside in the infirmary in weekly rotation.

Fees for all the Lectures required by the College and Hall, 47*l.* 5*s.* . Ditto, and for hospital practice, 87*l.* 5*s.*

PRIZES.

Suple Prize.—A gold medal, value 5*l.* 5*s.* with 7*l.* 7*s.* in money, is given annually to each of the two successful candidates in each of the medical and surgical examinations. Clark's Prize. See advertisement.

BIRMINGHAM.

QUEEN'S COLLEGE.

This College affords opportunity for education in all branches of knowledge.

PRIZES.

The Warnford Scholarships : four scholarships of 10*l.* each, held for two years, conferred for diligence and good conduct. The Warnford Gold and Silver Medals for essays of a religious as well as a scientific nature. The Founder's Scholarship, conferred on a first year's resident student after examination at the end of the summer session. Honorary medals and certificates of honour are annually given. The Percy and Clay Prizes of five guineas each, in books, for proficiency in the German and French languages respectively.

THE QUEEN'S HOSPITAL.

The hospital has lately obtained, by Act of Parliament, separation from the Queen's College, and will now be open on equal terms to the students of both the medical schools. Each physician and surgeon visits his wards with the students on an appointed day in each week, and special courses of lectures are given by each of the officers in succession. By these arrangements the students can follow the practice of each physician and surgeon during the whole of the Winter and Summer Sessions and in the same periods attend the special courses delivered by each clinical Professor.

For further particulars see advertisement.

LEEDS SCHOOL OF MEDICINE.

The magnificent New Infirmary, which attracted so much attention during the six months that it contained the National Art Exhibition, was opened for the reception of patients in May, 1867, and is now in full work.

THE HARDWICK CLINICAL PRIZE.

The prize, of the value of £10, is given for the best set of Reports of Medical cases in the Hospital during the Winter Session.

THE SURGEONS' CLINICAL PRIZE

For the best set of Reports of Surgical cases in the Hospital during the Winter Session. Competitors must have completed their first year. The Prize consists of Ten Pounds.

THE THORP SCHOLARSHIP IN FORENSIC MEDICINE.

This is a Prize of Ten Pounds, awarded at the close of each Summer Session.

CHEMICAL SCHOLARSHIPS.

Two Chemical Scholarships are offered annually ; one open to first year's Students entitled to three months' Laboratory instruction. The other, to six months.

For further particulars see advertisement.

SHEFFIELD SCHOOL OF MEDICINE.

This institution affords a complete medical education.

As a school for the study of diseases of the lungs and air passages, it stands, perhaps, second to none, on account of its proximity to some of the largest grindery and cutlery establishments in the world. In connection with the school is the Royal Infirmary, containing 150 beds.

For list of lecturers, fees, &c., students are referred to our advertising columns.

Regulations and Bye-Laws
of Licensing Bodies in England.

UNIVERSITY OF LONDON.

EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.

CANDIDATES are required—1. To have passed the matriculation examination of this University, or to have taken a degree in Arts in some other University, of the United Kingdom. 2. To have been engaged in their professional studies four years subsequently to matriculation ; one year, at least, of the four in the United Kingdom. 3. To pass the preliminary Scientific examination and two in Medicine.

The Preliminary Scientific Examination takes place on the third Monday in July. The candidate must have completed his seventeenth year, and have either passed the Matriculation Examination or taken a degree in Arts.

Fourteen days' notice must be given to the Registrar previous to the examination. Fee £5, which is not returned on rejection.

Any candidate who has passed the Preliminary Scientific Examination may, on the Tuesday and Wednesday in the second week after the pass examination, be examined for Honours in Chemistry and Natural Philosophy, and on the following Thursday and Friday in Botany and Zoology.

FIRST M.B. EXAMINATION

Commences on the last Monday in July.

A candidate must produce certificates to the following effect :—1. That he has completed his nineteenth year. 2. Passed the Preliminary Scientific examination at least one year previously. 3. Been a student subsequently to Matriculation during two years at a recognized medical school ; and that he has attended a course of lectures on three of the subjects in the following list :—Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Midwifery and Diseases peculiar to Women and Infants, Surgery, Medicine. 4. That he has subsequently to Matriculation dissected during the two winter sessions. 5. Attended a course of practical chemistry, comprehending the more important processes of General and Pharmaceutical Chemistry ; the presence and nature of poisons ; the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 6. That he has attended to practical Pharmacy.

These certificates must be transmitted fourteen days before the examination. Fee £5, not returnable on rejection.

The examinations for Honours take place in the week following the First M.B. Examination, and are conducted by means of printed papers. The Senate award three exhibitions of £40 per annum for the next two years, provided that the candidate declare his intention of presenting himself at the Second M.B. Examination within three years. Under the same circumstances, the first and second candidates in each subject receive each a gold medal of the value of £5.

SECOND M.B. EXAMINATION.

This examination commences on the first Monday in November.

No candidate is admitted within two academical years of the time of passing the first examination, nor without producing certificates :—1. Of having passed the first M.B. examination. 2. Of having subsequently attended a course of lectures on two more of the subjects specified. 3. Of having conducted twenty labours. 4. Surgical hospital during two years, and lectures on clinical surgery. 5. Medical hospital two years, with lectures on clinical medicine. 6. Of having, subsequently to hospital practice, attended to practical medicine, surgery, or midwifery, with special charge of patients, in an hospital, infirmary, dispensary, or parochial union, during six months. Certificates of moral character from a teacher in the last school at which candidates have studied. Fee, £5.

HONOURS AT SECOND EXAMINATION.

Any candidate who has been placed in the first division may be examined for Honours in Medicine, Midwifery, and Forensic Medicine.—In Medicine, £50 per annum for the next two years, with the style of University Scholar in Medicine ; in

Midwifery, £30 per annum for the next two years, with the style of University scholar in Midwifery; in Forensic Medicine, £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine. First and second in each subject, a gold medal of the value of £5.

N.B.—Candidates will be expected to write prescriptions in Latin, without abbreviations.

BACHELOR OF SURGERY.

The examination takes place once in each year, and commences on the fourth Tuesday in November. A candidate is admitted on producing certificates:—Of having taken the degree of B.M. in this University. Of a course of operative surgery, and of operations on the dead subject. These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for this examination is £5.

The examinations shall be conducted in the following order:—

TUESDAY, *Afternoon*, 3 to 6.—Surgical Anatomy and Surgical Operations, by printed papers. THURSDAY.—Examination, and Report on Cases, of Surgical Patients. FRIDAY, commencing at 1 P.M.—Performance of Surgical Operations upon the Dead Subject; Application of Surgical Apparatus; *Vivâ voce* Interrogation.

MASTER IN SURGERY.

The examination takes place the fourth Monday in November.

Candidates must produce certificates:—1. Of having taken the degree of Bachelor of Surgery. 2. Of having attended, subsequently (*a*) to Clinical Surgery two years in a hospital; (*b*) or to Clinical Surgery one year, and of three years in the Practice of his Profession; (*c*) or of five years in the Practice of his Profession. 3. Of Moral Character.

The examinations shall be conducted in the following order:—

MONDAY.—*Morning*, 10 to 1, Logic and Moral Philosophy, by printed papers; *Afternoon*, 3 to 6, a Commentary on a Case in Surgery, by printed papers. TUESDAY.—*Morning*, 10 to 1, Surgical Anatomy, by printed papers; *Afternoon*, 3 to 6, Surgery, by printed papers. THURSDAY.—Examination, and Report on Cases of Surgical Patients in the Wards of a Hospital. FRIDAY, at 1 P.M.—Dissection of a Surgical Region, or Performance of Surgical Operations; *Vivâ voce* Interrogation.

HONOURS IN SURGERY.

The candidate who shall distinguish himself the most in Surgery shall receive a gold medal of the value of twenty pounds.

Any candidate who has passed the B.S. examination may be examined for Honours in Surgery on the following Tuesday.

The candidate who distinguishes himself the most shall receive 50*l.* per annum for the next two years, with the style of University Scholar in Surgery. The first and second candidates shall also receive a gold medal of the value of 5*l.*

ROYAL COLLEGE OF PHYSICIANS, LONDON.

EXAMINATION FOR THE LICENCE.

EVERY candidate must sign a declaration, stating whether he has been rejected within three months.

The first examination, on Anatomy and Physiology, will be as follows:—First evening, seven to ten, written questions; second evening, seven o'clock, *vivâ voce*, on Dissections and Preparations. The Second or Pass examination will be as follows:—First evening, seven to ten, written questions on Surgical Anatomy, and Practice of Surgery; second morning, the candidate's knowledge will be tested, either at the college or in the surgical wards of an hospital; afternoon, one to four, on Materia Medica, and on Chemistry; partly by written questions, and partly practical; evening, seven o'clock, written questions on Midwifery and Diseases of Women; third, evening, seven to ten, written questions on Medical Anatomy, and Practice of Medicine, including Public Health; fourth morning, the candidate's knowledge will be tested, either at the College or in the Medical Wards of an hospital; evening seven o'clock, *vivâ voce*, on Practice of Medicine, Surgery, and Midwifery.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

PRELIMINARY GENERAL EDUCATION.

CANDIDATES who have not passed one of the recognized preliminary institutions will be required to pass an examination in English, Classics, and Mathematics, by the Royal College of Preceptors.

PROFESSIONAL EDUCATION.

Professional studies are not recognized prior to examination in general knowledge.

The following will be considered as the commencement of professional education:—Attendance on hospital, or other institution recognized by this college. Instruction as the pupil of a surgeon to a hospital, general dispensary, or union work-house, or where such practical instruction is afforded as shall be satisfactory to the Council. Attendance on lectures on Anatomy, Physiology, or Chemistry.

The commencement of professional study by pupilage will not be admitted until a certificate shall be furnished for registration at the college by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the hospital or other institution; and will, consequently, date only from the reception of such certificate, the certificate to be accompanied by proof of having passed the preliminary examination.

Candidates must produce the following other certificates:—Of being twenty-one years of age. Of having been engaged during four years in the acquirement of professional knowledge. Practical Pharmacy three months. Lectures on Anatomy during two winters. Dissections, two winters. Lectures on Physiology, two winters. On Surgery, two winters. One course not earlier than the third winter. One course on each of the following—viz., Chemistry, Materia Medica, Medicine, and Midwifery. Of instruction and proficiency in Vaccination. In the case of candidates who commenced after the 1st October 1863, the certificate in vaccination will only be received from recognized vaccine stations, or from recognized vaccine departments in medical schools or hospitals. Of having attended, at a recognized hospital, the practice of Surgery, and clinical lectures on Surgery, during three winter and two summer sessions, and the practice of Medicine, and clinical lectures on Medicine, during one winter and one summer session. Of having, after two years' professional education, taken charge of patients under a surgeon during six months, at a hospital, general dispensary, or parochial or union infirmary recognized for this purpose, or in such other similar manner as shall afford sufficient opportunity for the acquirement of Practical Surgery.

Certificates from a provincial hospital unconnected with a school, will not be received for more than one winter and one summer of attendance, and clinical lectures will not be necessary, but a certificate of having acted as dresser for six months instead.

Certificates will not be received from London students unless they register at the college their cards of admission to lectures and hospital within fifteen days from the commencement of the session; nor from provincial students, unless their names shall be duly returned.

Candidates who have studied in Scotland or Ireland will be admitted upon the same certificates required by the College of Surgeons of Edinburgh, the Faculty of Physicians of Glasgow, and the College of Surgeons in Ireland, together with a certificate in Vaccination, and evidence of four years' professional study.

Members or licentiates of a College of Surgeons, and graduates in Surgery or Medicine of a University will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate in Vaccination, and evidence of at least four years' professional study.

THE PROFESSIONAL EXAMINATION

Is divided into two parts. The first, or Primary Examination, on Anatomy and Physiology, is partly written, and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The second, or Pass Examination, on Pathology, Surgery, and Surgical Anatomy, and Medicine, is partly written and partly oral, and partly on the use of surgical apparatus. The Primary Examinations are held in January, April, May, July, and November; and the Pass Examinations generally in the ensuing week respectively. Candidates will not be admitted to the Primary Examination until after the termination of their second winter at a recog-

nized school; nor to the Pass Examination until after the fourth year. The fee of five guineas paid by each candidate prior to his Primary Examination will not be returned, but will be allowed on his admission as a member. A candidate having entered his name for either examination, who shall fail to attend the meeting of the court for which he shall have received a card, will not be allowed to present himself within three months from the date. A candidate referred on the Primary Examination is required, prior to re-examination, to produce a certificate of the performance of dissections during not less than three months subsequently. A candidate referred on the Pass Examination is required to produce a certificate of six months' surgical practice of a recognized hospital, together with lectures on clinical surgery.

APOTHECARIES' SOCIETY OF LONDON.

PROFESSIONAL EXAMINATIONS.

THE Examiners meet every Thursday at a quarter before four. Candidates must give notice before the Monday previous, and deposit the required testimonials, with the fee. The examination is divided into two parts, partly in writing, and partly *visà voce*.

FIRST EXAMINATION,

Which may be passed after the second winter, embraces the following subjects:—

Prescriptions.
Anatomy and Physiology.
General and Practical Chemistry.
Botany and Materia Medica.

SECOND EXAMINATION.

At the termination of studies:—
Principles and Practice of Medicine.
Pathology and Therapeutics.
Midwifery, including the Diseases of Women and Children.
Forensic Medicine and Toxicology.

Public Services.

POOR-LAW MEDICAL SERVICE.

In the first place, then, a young qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the Metropolitan Poor Act of last year, the English Poor-law Medical Service may be said to have been in the hands of the guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for medical relief. Union Medical Officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a medical and a surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications whatever else they may add to them. These appointments are not lucrative. In most cases the salary is very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and it will probably shortly be extended to the country. It establishes in London asylums and dispensaries, and distributes the cost of supporting them over the metropolis. The

appointment of the Medical Officer will be made by the Dispensary Committee, but the Poor-law Board has power to modify many of the arrangements. The Poor-law Board is now a permanent body with increased powers, but since the Act so few improvements have been effected that the Medical Officers are very dissatisfied.

IRISH POOR-LAW MEDICAL SERVICE.

UNDER this head we refer to the appointments of Medical Officers to Workhouses and Dispensaries. There are 163 workhouses and 793 Dispensary Medical Officers, besides apothecaries. The number of vacancies that occur annually average about 100. The average salary in this service is £90; and when it is taken into consideration that, in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, owing to their great area, some being over 150 square miles in extent, and having islands attached to them, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left. Great stress is laid on the fact that this sum does not include vaccination and registration fees. These, however, average but from £5 to 10 each in rural districts. Medical Officers are permitted to practise privately besides; but Poor-law medical relief is in most districts given with so little discrimination, and is in the hands of so many individuals, members of dispensary committees, wardens, relieving officers, &c., that almost any one can obtain it, no matter how unfit a subject he may be. Guardians themselves and their families often avail themselves of this laxity. And there is no redress, so that the consequence is, that the prospect of obtaining much private practice is not a very hopeful one whilst in the possession of a Poor-law medical appointment.

The qualifications required are a licence in Surgery or a diploma in Medicine, and a diploma in Midwifery; the candidate must also be twenty-three years of age.

Each district is under the direct control of a committee composed of the neighbouring landholders, the appointment of medical and other officers are made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Poor-law Commissioners, who have the power either of interposing their veto on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, and without the resource of appeal or investigation. This salary is paid by the Board of Guardians, and no increase or decrease can be made in the amount without their assent and that of the Commissioners. Under the late Sanitary Act the committee made recompense to the Medical Officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The qualifications for the medical charge of a dispensary or workhouse have, by a late order, been fixed at—a licence in Surgery, a diploma in Medicine, and a diploma in Midwifery, and the candidate must be at least twenty-three years of age. The number of unions in Ireland is 163, to each of which is attached a Medical Officer, who is appointed and controlled by the Board of Guardians in the same manner as the Dispensary Surgeon is by his committee. The salary is usually better than that of the Dispensary Doctor, and the duties of a more easy and satisfactory description.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law Medical Officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required. And whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential. And accordingly he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise in all probability any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in

very many instances the appointment is virtually made before the advertisement appears for a Medical Officer, in which case also candidates are put to unnecessary trouble and expense under false pretences. By an Act of Parliament which passed this year, Boards of Guardians may, at their discretion, grant superannuation allowances to their Medical Officer after twenty years' service, or when they are over sixty years of age, or if they are incapacitated from ill health.

For further particulars on this subject we would refer our readers to the "History and Working of the Irish Poor Law Medical System," which appeared in the *Journal of the Irish Medical Association* of the 9th and 16th December, 1868.

ARMY MEDICAL SERVICE.

For the present, the Army, which has hitherto provided a much sought after channel for the young surgeon, is closed to the profession. One of the economic reforms of the Government during the last Session of Parliament was to put a stop to the further appointment of Assistant-Surgeons, and to close the doors of Netley Hospital. The medical department of the Army is, however, well known to be very ineffective in respect of numbers, and the requirements of the service must, sooner or later, possibly next February, compel the authorities to call for medical recruits. We therefore reproduce the information on the subject at the date when the examinations were discontinued, which we have no reason to believe will be materially altered.

The appointment of Assistant-Surgeon in the Army is open to all who can prove their claim to it by superior answering. The Competitive Examinations are held at Chelsea, usually in the first weeks of February and August. The candidate is not required to produce any other qualification before presenting himself for examination, than his licences to practise and certificate of registration.

Having received his diplomata in Surgery and Medicine, both of which are essential to his competition, the student is obliged to apply himself vigorously to the study of certain collateral subjects, which he does usually through the medium of a "grinder." He must perfect himself in Chemistry, Pathology, and Comparative Anatomy, and if he can throw a proficiency in Botany and Natural History into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The Assistant-Surgeon is subjected to three separate Examinations within the first ten years of his service, each examination having a definite object. The first, to ascertain, previous to his admission into the service as a candidate, his scientific and professional education, and to test his acquirements in the various branches of professional knowledge. The second, after having passed through a course of special instruction in the Army Medical School, to test his knowledge of the special duties of an Army Medical Officer; and the third, previous to his promotion, to ascertain that he has kept pace with the progress of Medical Science.

The candidate having sent in his papers and followed them to London, meets his competitors at Chelsea. He is examined by Dr. Thomson on Natural History, Botany, Chemistry, and *Materia Medica*; by Dr. Parkes on Medicine, Midwifery, Therapeutics, Pathology, Pharmacy, and the writing of Prescriptions; by Dr. Pollock on Surgery and Surgical Appliances; and by Dr. Busk on Anatomy, Physiology, and Comparative Anatomy. Natural History and Botany are voluntary subjects. For the first two days of his examination he is employed in penning answers to printed questions; for the third and fourth days he is examined *vis à voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical

apparatus, and by operations on the dead subject. This trial finished, the successful candidates (varying in number from fifteen to thirty) are selected.

The following are the requirements as set forth in the official regulations:—

1. Every candidate must be unmarried, and not under 21 nor over 28 years of age. He must produce a birth certificate, or an affidavit from a near relative will be accepted. He must also produce a certificate of moral character from the parochial minister, if possible.
2. The candidate must make a declaration that he labours under no disease, imperfection, or disability.
3. The candidate must possess both a medical and surgical diploma, and be registered under the Medical Act.
4. Certificates of registration, character, and age must accompany this schedule when filled up and returned.
5. Candidates will be examined in Anatomy and Physiology, Surgery, Medicine, including Therapeutics, diseases of women and children, Chemistry and Pharmacy, and knowledge of drugs. (The examination will be in part practical, and will include operations, the application of surgical apparatus, and the examination of patients at the bedside.) Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*, and their marks will be added to the marks obtained in the obligatory examination, and the candidates' position on the list will thus be improved. His physical fitness will be determined by a Board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of Myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed.

SERVICE ON THE WEST COAST OF AFRICA.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, are offered appointments on the West Coast of Africa. These situations, while they are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home, on full pay, for every year spent in Africa, and the entire period at home and abroad counts as service for pension. The promotion is sometimes rapid, owing to the dangerous nature of the climate; and we have known the rank of full Surgeon reached in five years from the date of appointment as Assistant-Surgeon.

The following are the official regulations on this subject:—

A Medical Officer volunteering for service on the West Coast shall serve on the Coast for a period of at least twelve months, and shall be governed by the following regulations:—

Each year reckons towards promotion and retirement as two years of service, but it shall not so reckon towards increasing pay, or qualification for the rank of Surgeon-Major. If an Officer shall be permitted, at his own wish, to prolong his stay on the coast, his further service shall be allowed to reckon in proportion.

For each year's service on the Coast, a Medical Officer shall be entitled to a year's leave at home, and for every additional period beyond a year he shall have an equivalent extension of leave.

PROBATION AT NETLEY HOSPITAL.

The competitor who has been so fortunate as to obtain a place in the ordinary service is not allowed to join a regiment at once. He is obliged to undergo a probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures, viz.:—Hygiene by Dr. Parkes; Pathology by Dr. Aitken; Military Surgery by Dr. Longmore; and Tropical Diseases by Dr. Maclean. The lectures on Military Surgery include gunshot and other wounds; arrangements

for the transport of wounded; duties of Army Surgeons in the field, during sieges, on transport, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, clothing, &c., of the soldier; his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the Army Surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professors of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make *post-mortem* examinations, to operate on the dead body, and pass through laboratory practice on the modes of recognizing the qualities and adulterations of food, and on microscopic examination of morbid tissues and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings per day, and two shillings per day for lodging money, if he be not provided with lodgings in the hospital. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks; the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the Competitive Examination, and his position on the list of merit determined by the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of Assistant-Surgeons, as provided by the regulations.

Thus it will be observed that the first, or Chelsea examination, simply admits the candidate to the service, and the conjoined result of it and the Netley examination determines his order of merit.

THE PROMOTION EXAMINATION.

But there is still one other which *must* be passed before he is promoted to full Surgeoncy, and *may* be passed at any time after five years' service.

A series of printed questions will be sent by the Director-General to the principal medical officers of stations where Assistant-Surgeons may be serving, who will deliver these sealed questions to the Assistant-Surgeons, and to see that they are answered without the assistance of books, notes, or communication with any other person. The answers are to be signed, and delivered sealed to the principal medical officer, who is to send them, unopened, to the Director-General, together with a certificate from the Surgeon of the Regiment, or other superior medical Officer, that the Assistant-Surgeon has availed himself of every opportunity of practising surgical operations on the dead body.

The Assistant-Surgeon will also be required to transmit a Medico-Topographical account of the station where he may happen to be, or of some other station where he may have been resident, or else a Medico-Statistical report of his regiment for twelve months.

If the Examining Board and the Director-General are satisfied with the certificates and answers, and with the report, the Assistant-Surgeon will be held qualified for promotion.

The Pay and Retirement of Army Medical Officers are determined by the following Royal Warrant:—

1. The daily rates of pay shall be as follows:—

	£	s.	d.
INSPECTOR-GENERAL	1	10	0
DEPUTY INSPECTOR-GENERAL	1	7	6
SURGEON	0	17	6
ASSISTANT-SURGEON	0	10	0

	£	s.	d.
DEPUTY INSPECTOR-GENERAL	1	10	0
SURGEON-MAJOR	1	4	0
SURGEON	0	17	6
ASSISTANT-SURGEON, on appointment	0	10	0
Increasing 2s. 6d. per day each five years of service.			
APOTHECARIES	0	9	0
According to service.			

3. An Assistant-Surgeon shall pass the Promotion Examination, and serve on full pay for at least five years, before he can be promoted to the rank of Surgeon.

4. Assistant-Surgeons shall, as a general rule, be promoted by seniority, except in cases of distinguished service.

10. Good service pensions shall be awarded under such regulations as shall be from time to time determined. Six of the most meritorious medical officers of our army shall be named our Honorary Physicians, and six our Honorary Surgeons.

11. Medical officers shall have the right to retire on half-pay after twenty years' service; Surgeons-Major, Surgeons, or Assistant-Surgeons, shall be placed on the retired list at the age of 55, and Inspectors-General and Deputy Inspectors-General at the age of 65.

14. An Apothecary shall have the right to retire on half-pay after thirty years' good service.

HALF PAY.

18. A Medical Officer placed on half-pay by reduction of establishment, or in consequence of ill-health, or age, shall be entitled to half-pay.

	£	s.	d.	£	s.	d.	
INSPECTOR-GENERAL	1	10	0	to	1	17	6
DEPUTY INSPECTOR-GENERAL	1	7	6	to	1	5	6
SURGEON	0	11	0	to	0	13	6
ASSISTANT-SURGEON	0	6	0	to	0	10	0

19. The rate of half-pay awarded to officers on retiring for their own convenience, after twenty years' service, shall not exceed one-half of their full pay at the time of retirement.

20. Every Medical Officer who shall retire after service for twenty-five years, shall be granted seven-tenths of his pay, provided he shall have served three years in his rank or abroad for ten years, or for five years with an army in the field. An officer of twenty-five years' service, whose service falls within neither of these conditions, shall be entitled to only seven-tenths of the pay he was in receipt of prior to last promotion.

23. An Apothecary shall be granted pay at the following daily rate, if placed on half pay by reduction of establishment, or on account of age, or through ill health.

APOTHECARY TO THE FORCES, after thirty years' service, 5s. to 9s. a day.

NAVAL MEDICAL SERVICE.

The admissions to the Naval Medical Service are continued, and the closing of the Army Medical Department produced a greater degree of competition for Naval Assistant-Surgeoncies at the last examination than had existed for years. Hitherto the service had been in a condition of great depreciation. The competition for admission to it was inadequate to the filling up of the vacancies, and much discontent was evinced by some of the medical officers holding office in it. We have not been able to satisfy ourselves that the complaints of the disaffected are either universal in the service or well-grounded. We have knowledge of many gentlemen who have attached themselves to the service, and express their entire satisfaction with it, and of others who declare it to be unfit for a gentleman's occupancy. The special advantages of it in contradistinction to the army is, that its members are more likely to "see the world," and that the regular pay of the medical officer goes much further towards his support than in the army.

The official regulations for admission of assistant-surgeons are now under revision, and any information respecting them would be unreliable. There is, however, much unofficial detail of equal interest to the student, which we reproduce for his advantage from the pages of "Everything About Them," an instructive little brochure, published by Messrs. Edmonston and Douglas.

In applying to be admitted as an assistant-surgeon in the Royal Navy it is merely required to address a letter to the Secretary of the Admiralty, stating that you are in possession of a diploma from such a College—naming it; that you are of the required age, stating the same; and that you are desirous of being admitted as a candidate; when, if there are any vacancies, you will be informed when you will be required to present yourself at Somerset House, London, for examination.

Having passed your examination, you will, in the course of the following day, receive your appointment as acting assistant-surgeon to one of Her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. You will at the same time be informed that you are granted two or three weeks, as you may require, leave of absence, to enable you to provide your uniform and appointments. These you can get at any of the naval outfitters.

The expense of an assistant-surgeon's uniform is about £47 5s. These are credit prices, but would, I presume, be considerably less for ready money, a thing, by-the-by, to which naval tailors are not much accustomed. You must also provide yourself with a set of surgical instruments which will cost you from ten to fifteen guineas. All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from any naval outfitter.

ADVANCE OF PAY ON JOINING.

On joining your ship you will, if you wish it, be paid what is termed three months in advance, £30. Of course it is not all advance, as your pay will have been going on from the date of your appointment.

Every article of mess traps is now furnished by the Admiralty gratis. The same with your cabin furniture; every necessary article except bedding is supplied from the dockyards. An officer on joining his ship has, therefore, nothing more to pay than his mess subscription monthly. This varies in ships according to the station they are on, from £2 10s. to £3 10s. per month. This subscription does not include anything for wines or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted, by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board than you could the same qualities of wine on shore. The monthly subscription, of say £3, with the Government allowance of 11l. 3s. 8d. per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all wardroom messes to have an extra dinner on two days of the week—generally Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wine consumed. It is usual to invite the captain, and other superior officer that may be on board, once a week; the other public guests are so many of the junior officers of the ship; and, in port, officers of the sister service, and other public functionaries. The captain, or admiral, if there be one on board, usually has two or three wardroom, and two or three gunroom officers, to dine with him on every other day of the week than that on which he dines in the wardroom. Any member of the wardroom mess inviting a private friend to dine with him on board, pays usually from 2s. 6d. to 3s. 6d. (according to the rule of the mess) for his friend's dinner, in addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the wardrooms of Her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expense,

any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

SERVANTS.

Assistant-surgeons are allowed only half a servant each; or, in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officer's servant. Their pay from the Admiralty is about £17 per annum and their provisions; and where they are well-conducted, attentive lads, it is usual for each of their masters to give them 10s. a month, which makes their pay up to about £29 per annum.

The pay of naval medical officers has hitherto been the same as for their military brethren.

EXTRA PAY AND ALLOWANCES.

The following extra pay and allowances are paid to naval medical officers under the conditions stated below:—

	At Home.	Abroad.
Inspectors-General, in lieu of provisions for their servants, and of the ordinary allowance for provisions for themselves ...	£54	£180
Deputy Inspectors-Generals Staff-Surgeons, and Surgeons, do. do. do. ...	£35	£112
Assistant-Surgeons, do. do. do. ...	£30	£108

Staff-surgeons, when serving in flag-ships on foreign stations, are allowed extra pay of five shillings per diem.

Staff-surgeons, surgeons, and assistant-surgeons, when serving in ships in which there is no accommodation for residing on board, as in drill-ships for the Royal Naval Reserve, are allowed £50 per annum for lodgings, and one and sixpence per diem in addition in lieu of ship's rations.

Whenever medical officers are employed on extra duty, they are allowed such extra pay as it may appear to the Lords Commissioners of the Admiralty the nature of the service merits.

Medical officers, when travelling on the public service, are allowed on the home stations—in addition to all expenses of first-class fare by rail or otherwise—for subsistence:—

	Special Service occupying 12 hours.	Ditto for every 24 hours.
Inspector-General and Deputy Inspectors-General ...	£0 12 0	£1 0 0
Staff-Surgeons and Surgeons ...	0 7 6	0 10 0
Assistant-Surgeons ...	0 6 0	0 7 6

PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to medical officers, there are three good-service pensions of 10s. each per diem awarded to the three inspectors-general who have completed the longest and most meritorious services.

There is also one Greenwich Hospital pension of £80 per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of £50 each per annum, awarded to those fourteen deputy inspectors-general, staff-surgeons, and surgeons who are considered by the Admiralty to be most deserving of them.

PROMOTIONS.

An Assistant-surgeon having served three years may be examined as to his qualifications for promotion to the rank of surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an inspector or deputy inspector-general and three surgeons; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House, for his regular and final examination. To enable assistant-surgeons to pass this examination satisfactorily they are granted, on application, two months' leave of absence to prepare themselves for it. The use of passing the provisional examination abroad is, that the assistant-surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as acting-surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion as acting-surgeon will be confirmed as surgeon on passing the regular examination at Somerset House. If the vacancy

has occurred from any other cause than that of death, the assistant-surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as acting-surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a surgeon from half-pay.

Surgeons are promoted to the rank of staff-surgeons on twenty years' service, provided that ten years have been completed since passing for the rank of surgeon.

By an Admiralty regulation dated the 12th of July, 1867, promotion to staff-surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty-years' service.

An officer may be promoted to the rank of inspector-general on the completion of thirteen years' service from the date of his entry in the Royal Navy.

PRIZE-MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of customs, and to trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels; and of the rewards conferred for the same; as also in the awards of all salvage granted to the crews of Her Majesty's ships and vessels of war, with other officers of corresponding ranks.

THE ASSISTANT—HIS DUTIES AND OBLIGATIONS.

ALMOST every provincial general medical practitioner in England has his qualified or unqualified assistant, and the probationary service of the private practitioner himself is thus very frequently in this capacity. As may be presumed, the duties of the office are very various, and the relations between principal and assistant very complex, so much so as to demand a special volume for themselves, which, from the experienced pen of Mr. Langley, has recently issued in a revised form. We have availed ourselves of the author's very kind permission to extract from the pages of "Via Medica" certain passages which are essential to the student, and for the accuracy of which Mr. Langley's name is a perfect guarantee.

MEDICAL ASSISTANTS.

THE PUPIL ASSISTANT.

THE pupil-assistant is usually a young gentleman who enters into the service of his employer to learn pharmacy and the manipulation of dispensing without present remuneration, or who gives his services in return for board and lodging with a nominal salary. If there be any articles of apprenticeship, or any such indentures contracting for service as have before been mentioned, the relations between the junior and his employer are those which exist under apprenticeships generally, subject to the terms and conditions stated in the indenture itself. Whether there be such a contract in writing or not, the assistant, though a minor, can sue for the necessaries or salary (if any) agreed to be paid by his employer.

The *unqualified* assistant (without diploma) capable of visiting patients, diagnosing disease, prescribing, dispensing, attending midwifery, drawing teeth, bleeding, cupping, applying the tourniquet, opening an abscess, dressing a wound, &c., &c., is generally a young man who has passed through his pupilage or apprenticeship, seen something of country practice, spent a year or two at the hospital and medical school, and who, having limited means, desires to recruit his resources.

Qualified men (with single or double diploma) are generally required for *outdoor appointments*, in which the assistant does not reside with his principal. Indeed, it may be remarked that the tendency generally seems to be towards the employment of gentlemen with diplomata in preference to those without, because the employer is rendered more free to absent

himself, occasionally, if he can leave his practice in the hands of a substitute who can legally take charge of his parochial appointments, or, in case of accidents, give evidence before the coroner.

Constant applications are made by gentlemen from the "sister isle," who, having degrees in arts, honours in medicine, and high testimonials as to personal character, do not understand why they cannot at once obtain employment as assistants in England, in town or country practice. If they are asked what they know of private dispensing, they reply that they are competent to undertake anything of that kind *because they have done it at the hospital*. They cannot understand that aptitude in private dispensing—apothecary's work—is essential in English practice as it is at present conducted, and they are unwilling to believe that a mere power of manipulation is an absolute requisite if they would obtain employment here.

The prejudice against Scotchmen and Irishmen is general and deep-rooted in England. My experience, however, justifies me in asserting that I have found some of the best assistants I have ever known amongst the Irish Catholics, whom my clients have received under protest, but who have demonstrated by their conduct that varieties in religious opinion do not make much difference in man's capacity for duty.

It is almost useless for gentlemen from Ireland and Scotland seeking employment unless they can produce testimonials (those of college teachers will not suffice) from persons who know the applicants in private life, and who can give direct evidence as to their *private* character and personal habits.

THE OUT-DOOR ASSISTANT.

The "out-door assistant" is a gentleman who does not live with the principal, but who usually resides near the house of his employer. The term "out-door" is not intended to convey the idea that his duties are wholly "extern," but simply indicates his mode of life. The out-door assistant sometimes lives in lodgings at his own expense, sometimes in rooms furnished and provided by the surgeon for whom he acts, sometimes the rooms may be in the adjoining house where the "surgery" is, sometimes in a residence at some distance. In the latter case there may be a "branch practice" to be "conducted." In all cases where the assistant resides elsewhere than with the surgeon, proportionately larger salaries are given to compensate for extra expenses. These situations are supposed to afford greater personal freedom, but more completely exclude the holder from pleasant society. Where a branch practice is carried on, a separate house and surgery are provided at the expense of the principal, who in such cases may visit the locality only once or twice a week. Candidates for these appointments are expected to have a double qualification, and to be able to take sole charge of the cases entrusted to them. No one who is not thoroughly competent in midwifery should entertain the idea of taking a branch practice.

Assistantships, *with time to attend lectures, &c.*, are not unfrequently sought after. Formerly such appointments were not uncommon, but experience has shown that they work so badly both for surgeons and pupils that they may be said to be almost extinct.

THE LEGAL RELATIONS OF THE PRINCIPAL AND ASSISTANT.

The engagement of an assistant may be made by word of mouth or by writing. The usual written contract between the parties (where apprenticeship is not intended) is an agreement of the ordinary character; but in the case of unqualified assistants the engagement is verbal, or made by correspondence between the parties.

Arrangements are sometimes made under which assistants are paid a certain percentage upon the fees received by the principal for work done by his subordinate; and often in cases of branch practices, a proportion of the gross profits is awarded to the assistant.

TERM OF ENGAGEMENT AND DISMISSAL.

In cases where there is no written contract with a permanent assistant engaged nominally for the year, and the salary is paid *weekly*, it is the custom in the medical profession to give and require a *month's* notice. But in temporary engagements, such as those made for *locum tenens*, the invariable custom is to pay by the week, the contract being terminable at any time by the wish of the principal. In such cases the gentleman employed is always expected to give reasonable time—say seven days—to provide a successor, if circumstances induce him to wish to resign the appointment.

The apprentice, or the "pupil with indentures," is bound by

the terms and conditions of his "articles," which are generally to the effect that A. B., the pupil, will serve C. D., the principal, for a certain term of years without salary; C. D. in return providing A. B. with board and lodging, and instructing him in the business or profession of surgeon and apothecary. In these cases the contract between the parties cannot be terminated except upon the conditions stated in the deed.

In-door assistants, whether qualified or not, can be dismissed by a month's notice at any time, or by the payment of a month's salary by the principal; the assistant, however, who leaves without giving a month's notice is liable to summary punishment by a magistrate, nor would the tender of a month's salary in lieu of notice relieve him from this liability to punishment; moreover, he would also forfeit all claim to any salary due to him from his principal for any services rendered previous to his leaving.

The out-door assistant, if resident in a house or lodgings furnished and provided by his employer, can in like manner be dismissed or terminate his engagement by a month's notice; but if the assistant provide himself with lodgings, furnished by himself by the wish or with the consent of his principal, the engagement cannot be terminated except by three months' notice or equivalent salary, and this notice may be given at any time.

The services of gentlemen engaged for special services and temporary duties may be terminated without notice unless there is a special understanding that the engagement is for one day a week, or four weeks.

LEGAL OBLIGATIONS ON THE ASSISTANT.

Every assistant is bound by law to obey all the lawful and reasonable orders of his employer, and to be honest and diligent in the professional duties required from him; he is required also to pay proper respect to the principal. He is bound to take care of the property entrusted to him, and, if guilty of gross negligence, will be liable to an action.

Where an assistant is engaged on account of his fitness to perform certain duties (such as "to visit, dispense, and attend midwifery"), and turns out to be perfectly incompetent to do any one of these things, the principal will be justified in rescinding the contract at once, and discharging the assistant; and it would be of no avail for the latter to prove his "qualifications" in the highest walks of his profession, if he were incompetent to perform those duties.

Temporary illness will not afford justification to the principal to terminate the assistant's engagement; but if the latter be attacked with such illness as would render it impossible for him to return to his duties for a month or more, it is very commonly held in the profession (*mos pro lege*) that the engagement may be terminated by the payment of two weeks' salary and the expenses of the transit of the assistant either to his home or to the spot from whence he was engaged.

SURGEONCIES IN THE MERCANTILE MARINE SERVICE.

THE appointment of surgeon in sea-going vessels is much sought after by young surgeons who are desirous of seeing a little more of the world than school, college, or home have shown them; but the office is seldom held for more than a few years, or regarded as a permanent provision for life. These appointments are almost uniformly in the gift of directors and secretaries of companies, and of the owners themselves, with whom, as may be believed, personal influences are a better recommendation than any professional qualification.

The Peninsula and Oriental Service heads the list in respect of its eligibility, and admission to it is a matter generally quite outside the range of the unfriended candidate.

The appointment is made by the directors, and the surgeon is bound for three years' service. He is placed always at first on some of the lines at the other side of the Isthmus of Suez, and is drafted into the "home" service between England and Alexandria, as vacancies occur. The pay is at first twelve guineas per month, which is afterwards increased, and he is permitted to receive such fees as may be offered for attendance on passengers, whom, however, he is bound to attend

without charge, if required to do so. Occasionally large fees are paid by grateful patients; but usually the income from this source is not large, and less in the home service than elsewhere.

The surgeon can resign on giving a month's notice when on leave—*i. e.*, when his ship is laid up.

The Cunard and other American mail lines select their surgeons through the interest of owners and managers. The American ships are bound to carry American surgeons, and the English ships English medical officers. The pay varies from ten guineas per month upwards, and the arrangement may be terminated by the surgeon at any time that the ship is laid up. If, however, he has signed special articles, he will, of course, be bound by them.

The West India Mail Service admits candidates only between the ages of twenty-two and forty. A regular curriculum, similar to that required by the licensing bodies, is necessary, and a special examination in climatic disease is administered to the candidate.

The following is the scale of pay:—At entrance 100*l.* a-year, Senior Surgeon, 120*l.*, amounting with all fees generally to about 200*l.* When the ships are engaged on transport service the pay is doubled. Surgeons in the service have a private cabin and a boy to assist in dispensing. They mess in the saloon, and are found in every requirement free of charge. A pint of wine is included in each day's rations, or in lieu of it a payment of 1*s.* 3*d.* At entry surgeons are required to join vessels in the West Indies or Brazil, relieving surgeons longest out, and being themselves relieved in turn. The fees in this service are much better than in the P. & O. The Emigration Commissioners are now reducing their staff, and making no appointments to vacancies as they occur. Many of the trading ships which carry emigrants to New Zealand and Australia take surgeons only on their outward voyage, and call at China for silks and other freight on their way home. Surgeons to these vessels are paid only 25*l.*, and finding it impossible to obtain a passage home again are compelled to settle in the colonies which are accordingly overstocked.

European Communities.—There is a growing demand for surgeons for small European colonies, and several desirable appointments have thus been recently made. A number of colonists feeling the want of efficient medical advice subscribe an annual guaranteed salary of say 600*l.* These appointments have been made through the agency of Mr. Langley, of Lincoln's Inn Fields; as, however, they are few and somewhat lucrative, the communities are entitled to expect a high degree of education and intelligence in their medical attendant.

NOTICES TO CORRESPONDENTS.

Those Gentlemen who have so kindly forwarded us information and corrections, will please receive our best thanks.

Several Original Papers, Correspondence, Hospital Reports, Notices of Books, and other matter, are unavoidably held over.

COMMUNICATIONS, Enclosures, &c., have been received from Dr. Alexander Marsden, London; Dr. Johnson, London; Dr. Lory Marsh, Nottingham; Mr. F. W. Brown, Uppingham; Dr. Parvin, Cincinnati; Mr. Bewley, Medical Club; Mr. Warren Tay, London; Dr. Salter; Dr. T. More Malden, Dublin; Mr. T. C. Miller, Wrentham; Mr. Slater, City of London Hospital; Mr. J. Baxter Langley; Mr. J. P. Lecture.

ON THE USE OF THE SHORT FORCEPS IN MIDWIFERY PRACTICE.

DELIVERED IN THE

ROTUNDO DUBLIN LYING-IN HOSPITAL.

By THOMAS MORE MADDEN, M.R.I.A.,
Assistant Physician to the Hospital.

LECTURE II.

GENTLEMEN,—Having described the short forceps, and pointed out the cases in which it should be resorted to, at our last meeting, we have now to consider the manner in which this instrument should be used. It is a matter of great importance to apply the forceps properly; for although in the hands of a dexterous accoucheur this instrument is employed as easily, painlessly, and safely as the catheter, yet in the hands of an unskilful practitioner the forceps is a most dangerous implement; and therefore we must, before going further, consider carefully the successive steps of the operation.

In the first place, I would advise you, whenever it is possible to do so, to act on the time-honoured rule that a consultation should be obtained before the forceps or any other instrument is resorted to in midwifery practice. However, if you cannot obtain a consultation, do not on this account hesitate to use the forceps, if you are of opinion that this measure is required. In the second place, you may, if your patient happens to be a sensible, resolute woman, inform her, as well as her husband, that you are about to give her assistance. But if she is in a nervous, excited, irritable condition, I do not think it necessary to communicate this to her, and never to any of the throng of female friends, who, amongst the lower order in this country, delight in congregating in the lying-in-room; for women, under these circumstances, are very apt to become fussy, nervous, and troublesome, when the name of an instrument

is mentioned. Make a point, however, of always telling the husband or nearest relation what you are going to do, and having turned all the sympathizing friends out of the room except the nurse, you may proceed to the preliminary part of the operation. You must first ascertain if the rectum has been properly cleared out or not, and, if it has not, administer a purgative enema, and wait till it has operated before you do anything else.

The next point to be attended to before introducing the forceps is to pass the catheter, and this must be done even when we are assured by the nurse that the patient has made plenty of water. I have several times been told this in cases where I found the bladder so distended by the accumulated urine, a little of which had dribbled away and misled the nurse, that the progress of the labour was completely arrested by this cause. I had only to draw off the water to enable the head to come down without any further assistance. It is easy to conceive how readily, if under such circumstances the forceps were used, rupture of the bladder might be produced. Therefore, never apply the forceps until you have first introduced a catheter into the bladder.

A digital examination is then to be made, in order to ascertain the exact position of the head, and convince yourself of the fact that the os uteri is fully dilated or dilatable. This is always an essential preliminary to the introduction of the forceps, for since my appointment as Assistant Physician to this hospital, two cases have come within my own observation, in which the attending pupils sent for the Assistant Physician to apply the forceps, who, on his arrival found the os not at all dilated, the cervix being so thin, and so tightly stretched over the child's head, as to lead the attending gentlemen, who were, I may observe, both qualified practitioners, into a mistake, which, had they made and acted on in their own practice, would have probably proved fatal to their patients and would justly have ruined themselves.

The operator now sits down behind his patient, facing the perinæum, and introduces the index and first fingers of his right hand, previously smeared with lard, up into the vagina behind the symphysis pubis, and passes them round half the circumference of the pelvis on the child's

head, until he comes in contact with the ear, which is generally towards the left iliac region, and sometimes on the right or towards either side of the pelvis. The ear should always be felt distinctly before the short forceps are introduced, and although some recent writers do not approve of this rule, yet I always act on it in my own cases.

The reasons for applying the forceps over the ear are, that the instrument, fitting better over the sides of the head and face, exercise a more equable pressure on the head, and are less liable to slip than when placed in any other position.

Before being introduced, the forceps must be brought as nearly as possible to the temperature of the body, and it is usual to immerse them in warm water for this purpose before they are applied. However, everything that adds to the fussiness of those about the patient should be avoided; and for this reason I now follow the practice recommended by Dr. Johnston, and never exhibit my instruments until I am applying them. The forceps will be sufficiently warm, if the practitioner keeps them, as I always do, in a pocket constructed for the purpose in his waistcoat, and my forceps are so small that there is no inconvenience in this.

The instrument is now to be smeared with lard, and the upper blade, the first to be introduced, is taken in the operator's left hand, and, being held as lightly as a writing pen, is, during an interval in the pains, to be slowly insinuated by a gentle, wavy motion, between the two fingers of the accoucheur's right hand, which, as I have already said, rest over the ear and the child's head, until it has passed so far up that the lock lies close without the perineum. The anterior, or pubic blade, is always introduced first in this hospital, but in England the reverse is generally the case. The instrument must, in the first stage of the process, be passed upwards and backwards in the direction of the lower axis of the pelvis, but almost immediately it must be turned in the axis of the upper portion of the pelvis, upwards and forwards.

The point of the blade is to be kept in contact with the fetal head, as the moment it diverges from it, the least degree of force might drive the instruments through the vesico-vaginal or recto-vaginal wall, the direction of the point being determined by the angle at which we keep the handle, so that, except at the moment that the instrument passes over the ear, when the handle must be depressed a little during the introduction of the blade, the handle should be gradually raised as the forceps slides over the convex head of the child.

The handle is then to be given to an assistant to retain *in situ*; the operator, holding the instrument with the right hand, introducing two fingers of the left in the same manner as before, passes up the other blade of the instrument, until the locking parts of both are opposite each other, when, having passed the finger round the lock to guard the soft parts from being caught by it, the forceps may now be locked.

In locking the forceps, as in its application, force is unnecessary and unjustifiable. If the blades have been properly introduced and applied to the head, there will be no difficulty whatever in locking them. If they are not properly adjusted, no degree of force can be of the least use, and as it is essential that the forceps be properly locked before any attempt at extraction is made, if there should be any difficulty in locking, no time should be lost in trying to bring the instrument into apposition, but the blade last introduced must be at once withdrawn, and re-introduced in the right position.

The extraction of the head is generally the easiest part of the operation. The operator, bearing in mind that the axis of the pelvis is a curved line, the axis of the inlet being downwards and backwards, and that of the outlet being downwards and forwards, makes his traction to correspond with this. At first he pulls downwards and backwards, and, as the head descends, alters the direction of his force until the head comes to distend the perineum, when he draws the head directly forwards.

As a rule, delivery with the forceps should be as close an imitation of natural labour as possible,—that is to say, bearing in mind that in natural labour the advance of the head is so slow and gradual, that the progress effected by each pain is almost imperceptible, the forceps should be so gently used as to imitate in the slowness of its action the course which nature herself points out.

The powers of the instrument should be exerted in the most gradual manner, except in certain cases of complex labour where immediate delivery is essential, and no attempt at finishing a tedious labour by any sudden and forcible effort is justifiable; nor should any desire to relieve his patient from suffering, or himself from a wearisome task, induce the practitioner to attempt by force what time, patience, and skill, can alone safely accomplish.

The old rule of waiting for a pain before commencing to draw down with the forceps, and of acting in concert with the uterine expulsive efforts, is obviously well founded, and should be acted on whenever the pains have not ceased before the forceps have been applied.

As soon as the occiput escapes from the vulva, it is generally advisable, in order to prevent the risk of lacerating the perineum, to trust the case to nature, and if there be sufficient uterine action to accomplish the labour, the instrument should now be unlocked, and the posterior and then the anterior blade gently removed, and the head forced out by pressing well on the perineum during the pains.

After the head has descended into the pelvic cavity, the short forceps may be used in three different positions.

1st. Where the head is delayed at the outlet, the face lying in the hollow of the sacrum, the occiput under the arch of the pubis, and the sagittal suture lying in the perineum, the ordinary position at the end of the second stage of natural labour.

2nd. When the labour is delayed by the malposition of the head, the face being turned forwards towards the symphysis pubis, the occiput and vertex being opposed to the sacrum and perineum.

3rd. Where the face lies to either side.

In the first position, delivery according to the rules already laid down is generally easy enough. In the second variety of position, the lock will be at the vertex and the point at the chin, and, by depressing this, the occiput will be drawn forwards from the perineum. The management of the third position demands no special mention.

Forceps cases require to be very carefully watched during the period of convalescence after labour. As a rule, if the operation has been properly performed, the recovery of the patient will be as speedy and perfect as after a natural labour. But, even after the best obstetric operations, peritonitis, metritis, puerperal fever, inflammation of the pelvic structures may follow an instrumental delivery. This fact should be borne in mind, so that the moment the earliest premonitory symptom of any of these diseases manifest themselves, they may be at once met with the appropriate treatment. After all cases of protracted labour, and especially after forceps cases, the state of the urinary function should be watched closely for the first few days, and if there be any retention, the catheter should be used at least twice a day.

This finishes all that it appears to me necessary to say about the use of the short midwifery forceps. I have only to add, that if the principles I have endeavoured to impress on you be correct, and if you now acquire, as you may easily do in this Hospital, the necessary manipulative skill, by observing others apply the forceps in the labour wards, as well as by practising yourselves with the instrument on the dummy in the lecture-room, you will find it hereafter to your own advantage, as well as that of your patients, to use the short forceps more frequently than is usually recommended; bearing always in mind, however, that in resorting to any obstetric operation you should act "*nec temere nec timide.*"

Original Communications.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 139.)

HEAT APOPLEXY.

UNDER the term *heat apoplexy* I would include the affections severally described as erythismus topicus, coup-de-soleil, apoplexy of the hot winds, sun-stroke, &c., &c.; for although, according to some authors, an essential difference exists between them, my own experience induces me to believe that they are in reality identical—all mere manifestations of derangements in vital functions arising from similar causes, but modified by conditions in which their subject is at the time placed. In all, the symptoms are the same, the treatment alike, and the *post-mortem* appearances undistinguishable, while in none are they sufficient to account either for the indications present during life, or for the fatal result in persons who die.

In former years the disease was attended by frightful mortality. In the 10th Regiment, for example, 28 cases were recorded as having occurred prior to 1857, one patient only surviving, and he so shattered in health as to have been unfitted for further service. Some other corps suffered far more severely than this from the disease, the recoveries being no more numerous relatively. I cannot help thinking that the greater prevalence of spirit drinking in former years, as compared with more recent times, conducted in a great measure to this prevalence and mortality; while among other circumstances which led to the same result may be enumerated the overcrowding of men in barracks then practised, the want of artificial means of cooling their rooms, and the system of enforced confinement of the soldiers to their barracks without any means of occupation or amusement during nearly twenty out of every twenty-four hours throughout several months of the year. Thanks to the frequent and energetic representations of army medical officers all such conditions are now much improved, if not altogether done away with; and the result is a material decrease in the prevalence of this disease, as well as of some others to which, in the course of these notes, allusion has already been made. In fact, we learn by the Departmental Blue Book for 1866 that, during the year, only 162 cases of the affection were recorded in the army serving in India, of which number 72 were fatal.

I believe that the term "sun-stroke" first applied to the malady was unfortunate, and that it has been productive of error in the manner of managing the sanitation of soldiers. Needless fear of simple out-door exposure was fostered by reason of the appellation. The facts must have been patent formerly, as they still are, that the victims of attacks were most numerous among soldiers who were compulsorily confined, whether in barracks, cells, or hospital; and that indigo planters, as well as other Europeans whose vocations necessitated much out-door exposure, were seldom subjects of sun-stroke. Yet I question if the opinion be even now quite exploded, that the only means by which soldiers can be protected from this disease is their seclusion in darkened and imperfectly ventilated rooms, such as barracks afford, notwithstanding all the more recent improvements in their construction.

Doubtless, the truth of these views was sorely tried during the mutiny. It was amply shown, during the operations connected with that outbreak, that soldiers could perform long marches and fight battles in the hottest weather without necessarily being attacked by this disease, although, on the other hand, they were under certain conditions extremely prone to its attacks. Thus it was found that, so long as the men were absolutely without ardent spirits or other intoxicating drinks, and were provided on the line

of march with an abundant supply of water, they could undergo a very considerable degree of exertion under the fierce sun of an Indian summer; and here I may observe that, on some of the longest marches in the hot season, it was found necessary to have elephants, camels, and bullocks carrying skins filled with water, brought along with the regiment; and men as well as officers, all alike lightly clothed, were in the habit from time to time of allowing a free stream from those skins to fall upon them, soaking them from head downwards. By such means the functions of the skin were maintained, and the temperature of the surface kept at a moderate elevation. Among other effects also produced was probably the supply by this means of oxygen to the blood circulating in the superficial capillaries. On the other hand, however, it was found in the case of some corps that men when debilitated, whether by insufficient food, by long-continued physical fatigue, or morally depressed through only partial success against the rebel enemy, were by no means thus exempt from its attacks; while the well-known liability to the disease manifested by men sick in hospital and undergoing punishment in cells may be accounted for on the same principle.

With regard to the period of the day at which persons are most liable to become attacked by the disease, I believe experience indicates this to be chiefly the later part of the afternoon and early part of the night. In either case the seizure is most to be dreaded during the time its subject is asleep, and especially when upon exhaustion is superadded heavy meals or potations of spirits. But, then, it by no means happens that cases of the disease are in proportion to the heat of the weather. Dry heat, more especially if the atmosphere be in rapid movement, is not so productive of attacks as a more moderate temperature, with a high ratio of aqueous vapour in suspension, and an absence of wind. Under such circumstances, and when the sky becomes obscured by dark negatively electric clouds, cases are tolerably certain to occur if the temperature in the shade be 97° F. and upwards; and, in fact, old residents come to know by their own sensations the conditions under which those who are predisposed to the malady are most liable to its attack. In the far inland districts of India, for example, all recognize such conditions in those calm sultry days which occasionally occur during the period of the hot winds, when the sun is obscured by a film of cloud, or by the impalpable dust suspended in the atmosphere. Nor is it man alone who, under such conditions, becomes subject to the disease; domestic animals, quadrupeds, and birds suffer equally with him, and the longer a dust or thunder storm is then delayed, the greater will be the mortality by the affection.

Medical officers are aware that many cases occur, especially during the hot and rainy season, in which it becomes difficult to decide whether the symptoms of the patient are referable to remittent fever or to heat apoplexy; while in others, symptoms which appear to characterize only the former run into the more dangerous conditions of the latter. From this circumstance alone, however, I question if we may rightly conclude that the origin of the "apoplexy" is traceable to malaria; in fact, there appears to be every reason for the belief that such is not the case, but that the affection, as well as the ardent fever, primarily arise from conditions of the atmosphere altogether unconnected with the presence of paludal emanations, inasmuch as the prevailing high temperature under which it occurs is destructive of such emanations—a circumstance which, as already observed, indicates a want of identity between the actual nature of the ardent remittent and the marsh remittent fever prevailing in different parts of the country.

I have remarked that, in the case of men, the affection is of common occurrence among those who, from whatever cause, remain much in confinement. In the case of women, however, this is different, and it is of some importance to note the circumstance. There were in the 10th Regiment an average of ninety soldiers' wives annually, and during twelve years no case of the affection is mentioned as having occurred among them. An explanation of this exemption

is doubtless to be found in the nature of a woman's occupation in-doors, as compared with man's. The wife, in performing the duties connected with her establishment, however small it may be, has sufficient bodily occupation to employ without fatiguing her, at the same time that her attention is also engaged; whereas, the soldier who voluntarily spends his time within doors is usually idle, perhaps a glutton or a drunkard; he passes the hours in idleness or in sleep; and the latter habit indulged in after heavy meals or a debauch of drink is one of the most powerful among the predisposing causes of the disease. I may here remark that, so far as I am aware, the wives of officers under the ordinary conditions of their class enjoy complete exemption from the affection.

It is a fact which deserves to be noted that, throughout the operations in the field in which the 10th Foot was engaged in connection with the Indian mutiny, no case of heat apoplexy among the men is recorded in the hospital records from the 1st of April, 1857, to the 31st of March, 1858. Other regiments were, however, less fortunate, and in one corps a heavy loss by the disease occurred among a detachment of men who, after a debauch during the night, marched during a day in the hot season, heavily accoutred and thickly clothed. But in the three succeeding months of 1858 our soldiers were not so exempt from the disease. By that time they had become physically lowered to a considerable extent, and thus their predisposition to attack increased. In a strength of 535 men, eleven cases occurred during April, May, and June, 1858, of which two only proved fatal. This proportion of mortality, if compared with that in previous years, might at first sight give rise to the impression that the attacks which happened were relatively slight. Such, however, was by no means the case; on the other hand, none were referred to heat apoplexy, except those in which actual insensibility was present.

The manner in which the attack by the disease occurs is various. In a considerable number of cases the person during sleep seems to pass gradually into the affection, the first indication of which is discovered in his stertorous breathing, and the intense and peculiar heat which prevails over the surface generally; in others, the affection, as already observed, supervenes upon a paroxysm of fever, the line of demarcation between the one and the other being often drawn with difficulty; in a third class of cases, the approach of the attack is indicated by the vacancy of expression, flushed face, and unusual behaviour of the patient; and in yet another class of cases, the person threatened with the attack is himself the first to mention the peculiar sensations which he experiences; these being, for the most part, weakness in and want of power over the lower extremities, involuntary micturition, giddiness or fulness in the head, and confused ideas. During the time of the mutiny, several instances of the latter occurred among officers, as well as among men, but by the early and free use of the douche the further advance of the disease was checked. The cases were not recorded as those of heat apoplexy, because the conditions had not become complete; but I do not now remember that of any person thus affected who had not to be sent to England at the first favourable opportunity. It is, no doubt, of such that we are accustomed to hear a good deal as having suffered from sun-stroke, and although a large number make speedy and perfect recoveries in the more favourable climate of Britain, it is beyond question that many others remain in the state of invalids for years.

(To be continued.)

Hospital Reports.

ROYAL VICTORIA HOSPITAL, NETLEY.

SOME very interesting cases are recorded in the new Army Blue Book by Professor Maclean. According to custom, we shall condense some of these, for the benefit of our readers. This week we give the following:—

Aneurism of Thoracic Aorta; Death from Exhaustion; Clear Syphilitic History.

Private W. Mills, Cape Mounted Rifles, admitted 19th May, 1867; died, 23rd May, 1868.

Suffering on admission from dyspnoea, palpitation of the heart, aphonia, and great pain in the chest and back. States that in 1856 he received a severe kick from a horse in the chest, and never did another day's work.

Examination by laryngoscope demonstrated that the aphonia did not depend on disease of the larynx. Aneurism of the thoracic aorta diagnosed from the constitutional and physical signs, confirmed by the appearance, in March, 1868, of a pulsating tumour synchronous with the first sound of the heart, at the level of the last dorsal vertebra. A distinct bruit was audible over the tumour. The aphonia increased, and the patient was much distressed by dyspnoea, dysphagia, and pain in the back, the latter symptom requiring the frequent use of the subcutaneous injection of morphia.

The tumour increased rapidly, exhaustion became extreme, with numbness of lower extremities. Death from exhaustion took place on the 23rd of May, 1868.

Lungs.—Left lung much consolidated. Right lung displaced by the aneurismal tumour; slight pneumonic infiltration of both lungs; lower part of left lung absorbed and adherent to aneurismal sac.

Pericardium considerably dilated, and filled with fluid of a sero-purulent character. Evidence of hæmorrhagic pericarditis and effusion of lymph on the surface of the membrane.

Heart pushed over to the right side, right cavities dilated, valves healthy, muscular texture soft and flabby.

Aorta much diseased; atheromatous degeneration commenced just above the valves, and extended not only as far as the aneurism, but also into the carotids.

Aneurism commences just below left bronchus; aorta opens into tumour by a valvular orifice near the middle of the tumour, passing for some distance beneath the inner coat. The tumour has dilated itself upwards and to the left side, and extends as high as upper margin of fourth rib, and downwards as far as last rib. It has expanded the diaphragm, causing a great distance between the aortic and œsophageal openings. The dilatation of the aorta extends as low down as the celiac axis. The aneurismal tumour was the size of a large cocoa-nut, and contained coagula; œsophagus and pneumogastric nerve were pressed down upon by the tumour. The whole posterior wall was made up by the vertebral column and ribs. There was erosion and softening of the three lower dorsal and first lumbar vertebræ; the ribs corresponding were dislocated and carious.

Aneurism of Thoracic Aorta; Habits Intemperate; Distinct Rheumatic and Syphilitic History; Death from Exhaustion.

Private Michael Kenelly, Royal Artillery, aged thirty-four. Admitted, 19th July, 1867; died, 5th October, 1867.

This man was invalided from Bengal, for rheumatism and asthenia. The man's character was bad, his habits were intemperate, and he had done no duty for months before he was sent home.

On admission, an aneurism of the thoracic artery was clearly made out by the constitutional and physical signs—in fact, it was visible to the eye, in the shape of a pulsating

HYDROPHOBIA.—Several cases have recently occurred in Yorkshire. One of these, a fatal case at Huddersfield, was a boy named James Henry Boothroyd, five years of age. He was bitten by a rabid dog in July last, and his wounds were attended to by a surgeon, and it was hoped he would recover; but symptoms of hydrophobia made their appearance last week, and he died in a day or two.

tumour to the left of the sternum; absorption of the sternal ends of the second and third ribs having taken place, allowed a portion of the tumour, the size of a large orange, to protrude. The patient sank from exhaustion on the 5th of October, 1867.

Lungs.—Both adherent to each other and to the tumour, from which it was impossible to separate the right; posterior portion of left lung much consolidated, from pressure of tumour.

Aneurism.—On removing integument from thorax, coagula were seen protruding through a large irregular opening, caused by absorption of the second and third ribs, near their sternal attachment. The sternum was removed, and the sac of a large aneurism thereby opened. The outer wall of aneurismal tumour was inseparably joined with periosteum of the sternum, and by pressure had caused caries of that bone. The site of the aneurism was in the anterior mediastinum, inseparably connected with both lungs and pericardium, globular in form, as large as a cocoon; it sprang from the aorta, near the origin of the *arteria innominata*, from its anterior wall, communicating with the aorta by an aperture the size of a florin.

Limits.—as high as first rib, and rather to left of median line. Lined by firm decolorized coagula; sac very thick, composed of fibrous tissue.

Superior vena cava inseparably connected with the tumour, which had also altered the course of the pneumogastric nerve and its branches, spreading them out over the sac.

Pulpy degeneration of intercostal muscles on left side; degeneration of cartilages of ribs, caries, and absorption of manubrium, and second and third ribs near sternal attachment.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

MERCER'S HOSPITAL.

FRACTURE OF THE PATELLA.

TREATED BY MALGAIGNE'S HOOKS.

By MR. MORGAN, F.R.C.S.I.,

Surgeon to the Hospital, and to the Westmoreland Lock Hospital, Dublin, Professor of Surgical and Descriptive Anatomy, R.C.S.I.

MR. STAPLETON'S case of fractured patella, related in a late number, illustrates a simple mode of treatment by straps of plaister, &c. As several cases have been treated with much success within the last year at this hospital by Malgaigne's method of approximation by means of hooks embracing the fragments, and as I have had under my care a case where now nearly a year has elapsed since the accident, the following details are of interest, as showing a very perfect recovery.

P. D., a racket-marker, when tipsy fell and fractured the patella by direct violence, as, on admission, the trousers were broken opposite to the fracture, and the skin was abraded. There was a T fracture of the patella, the lower fragment being split vertically, and there was considerable swelling. The limb was placed temporarily in an elevated position, and the fragments retained tolerably in their place by bandages. On the day after, I applied Malgaigne's hooks, fixing them well into the fragments, and drew them together till complete apposition was attained; the leg was put in a moderately elevated position, and a cold lotion applied. From this date, to use the patient's own expression, he "never had five minutes' uneasiness," and at the end of six weeks the parts were examined carefully, when very perfect union was found to have taken place. The hooks were removed and plaister straps substituted, and he was allowed gradually to use the limb. He subsequently got an attack of bursitis, which lasted some weeks, and arose from his making too free.

I saw him several times last winter, eight months after

the accident; the fragments were in perfect apposition, and the union *seems* altogether bony; there is not the slightest mobility between the upper and lower parts of the patella; he ran up and down the room for me, and is able now to follow his occupation as racket-marker, and to engage in the game, at which he is active.

The hooks in this case answered to perfection; and I may mention in four other cases which have been in the hospital since then.

The only inconvenience I found was the pressure of the connecting bar between the hooks on the tumefied skin; this can be obviated by taking care that it is well elevated over the surface of the patella, and by inserting some wadding or lint.

The hooks were applied within forty-eight hours of the occurrence of the accident, and cold lotions were sedulously applied to reduce distension, and the subsequent attack of bursitis had no connection with their application.

CANTHARIDES IN CHOLERA.

FORTUNATELY for those of our brave soldiers, whose fate it may be to be stricken with cholera in the future, a plan of treatment is slowly, but surely commending itself to the judgment of medical practitioners, which cannot fail, I firmly believe, to diminish the appalling death-rate which now prevails where European soldiers are attacked by this fearful foe. I mean, the plan of administering *diuretics* freely; aye, and not only the milder therapeutical agents of this class, but the very strongest, viz., cantharides. The plan of giving cantharides in cholera is not so recent as some would suppose. I have, lately, seen a Memorandum on the disease, written by a Madras medical officer, Assistant-Surgeon Ford, in 1851, in which he states, that he had employed the *Pulv. Canth.* in combination with creosote, for eight years previously, and that the natives were always clamorous to have it used in all cholera epidemics. Dr. Ford speaks of his experience as extending to the prisoners in the jail, and the city population, besides the 7th N. L., of which he was also in medical charge. Whilst Dr. Ford modestly states that, in his own practice, the death-rate was not, at all events, higher than what it was under other modes of treatment, in the hands of his native subordinates it was, according to them, next to nothing.

It would appear that in Madras, cantharides is recognised as an efficacious remedy in cholera; for, in Circular No. 728 of 25th February, 1867, issued from the office of the Inspector General of Hospitals in that presidency, a *cholera pill*, in which it is an ingredient, is recommended for distribution in outbreaks amongst the people, as the well known admirable pill—originally advocated by Dr. John Murray—is supplied to non-medical public functionaries in Bengal. This pill, however, contains opium. There are two kinds of cholera pill directed to be used in Madras, one with, the other without, opium. The latter contains cantharides, the former does not. There is a limit, necessarily, to the exhibition of the one which contains opium, whilst the other may be given much more freely. In the hands of an ignorant public, the opium pill is full of danger; not so the cantharides pill: and this point is dwelt upon by the Madras medical authorities.

This pill is made as follows:—Plumbi acetii, two ounces and two scruples; calomel, one ounce and one scruple; camphor, one ounce and one scruple; chili powder, one ounce and one scruple; pulv. canth., two drachms and two scruples; pulv. aromat., four drachms and four scruples. Dissolve the acet. of lead and cantharides in two drachms of acetic acid, and the camphor in some alcohol, when they are to be rubbed up with the calomel, the chili, the aromatic powder, and a sufficient quantity of distilled water, and divided into 1000 pills. One or two for a dose.

Two or three years ago, cantharides was, for the first time in Bengal if I recollect right, introduced by Mr. P. Webber, when Civil Surgeon in Assam. He reported that his success was marvellous; and I am convinced that the remedy will become a favourite one in time with the profession, from the fact of its being occasionally met with in prescriptions even now. I have, more than once, addressed the profession in the columns of the *Indian Medical Gazette* on the subject of the treatment of cholera, with, I rejoice to say, more or less success.

It is, nevertheless, a step in what, I venture to think, is the right direction.—Dr. Francis in *Indian Medical Gazette*.

Literature.

SPECIAL REPORT

ON

STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. I.

THE Student who has digested the information and advice offered him in the last issue of this Journal possesses the necessary data from which to form an opinion as to the School of Medicine⁶ which will best supply his wants. In the present day, however, the printing press is doing more than ever to supplement and, in some instances, to supersede oral instruction. Manuals, class books, and other works specially adapted for students' use, are being continually multiplied; and as the choice is not unlikely to present considerable difficulty, the Editors of the MEDICAL PRESS AND CIRCULAR have determined to furnish a report on the best text books. This, they believe, may be as useful a guide as the Students' Number is acknowledged to be in other matters; and they beg *in limine* to thank those gentlemen who have so kindly aided them in carrying out their idea, and to say that any further information with which they may be favoured will receive full consideration from those engaged in arranging the report, and, if found suitable, incorporated in the parts that will follow.

It is undeniable that there is a growing tendency in influential quarters to restrict the number of lectures that the medical student is compelled to attend. This does not arise from a want of confidence in the value of such teaching or in the ability of our lecturers, which was never more conspicuous; but it is felt that the array of excellent books on all subjects affords a diligent student opportunities of acquiring theoretical knowledge of which he should be at liberty to avail himself as far as may suit his taste. No one questions the necessity of oral instruction of a practical kind, and in this respect the majority of medical teachers are keeping pace with the advance of opinion by making their lectures as practical as possible. It may fairly be added that the vast majority of young men will always find that they can learn more quickly and more agreeably from the living voice of an able professor than from the silent and unsympathising forms of type, over which it is far easier to nod than it is while an earnest lecturer is demonstrating to his class the salient features of a subject. At the same time, reading must supplement the lectures; the manual is the necessary complement to the professor. No teacher can impart his knowledge to an inattentive pupil. Bodily presence in the class does not of necessity imply mental attention, without which nothing is to be gained. So afterwards, the lecture heard should be thought over, the notes taken referred to, and the subject gone over afresh with the text book. Without reading it is scarcely possible to make due progress; and we would urgently press upon every student the absolute necessity of devoting some portion of each day to his manuals. The student's evening should not be frittered away in vain amusements or idle gossip. Not that we would wish him to deny himself occasional relaxation, nor that we would in any case sacrifice a proper

share of out-door exercise, so necessary to health. Still, the student should never forget that his time is very short, that he has to accomplish much in a brief period, and has therefore great need to redeem the time. At least half his evenings should be consecrated to reading, and we are inclined to think he would gain most by devoting two hours every week evening to this purpose. From seven or eight o'clock till ten four or five nights a week ought not to weary a student, and then let him go to bed; for "early to bed and *early to rise*" is a wise maxim for students to follow.

The library of the student is necessarily, to a large extent, composed of the kind of books of which we now propose to speak; and the more varied it is the better. We should be sorry to discourage those whose means are limited. For a small cost they may obtain a library large enough to meet their absolute necessities. But we would advise everyone to make books the last item in economising. Be careful to buy *good* books; but in their number let there be no stint. We commend those who take pride in their libraries. Such pride may well take the place of many other more expensive tastes, and the study of two or three books on the same subject will give a variety to the work, the charm of which remains unknown to him who confines his reading to a single manual. To be a little more particular, a man who has plenty of money may by degrees possess himself of most of the best works for his purpose, and read them in turn with pleasure and profit. But most students have not so much money to spare, and we must therefore endeavour to assist their choice. Those who can only afford a single manual on a single subject should be very careful to buy the best, even if it cost more than another nearly as good. Those who can afford two works on each subject should take, as it were, one of each sort,—a small and a large one. The smaller is the genuine text book; the larger is a more complete treatise, not unfrequently founded on, or consisting of, a course of lectures. For example, one of the manuals on Medicine being selected, a larger work, such as Watson's inimitable Lectures, of which we hear a new edition will soon appear, should be purchased, or else Aitken's "Science and Art of Medicine," the most complete guide for students and young practitioners in the English language, and the one, therefore, which should be selected by all who desire to afford only one class book on medical practice.

So, again, in Surgery, the small manual *par excellence* is Druitt's "Vade Mecum," of which we hear a new edition will be ready next month; and in this particular instance we would advise every student to obtain this work, whatever others he may also add to them. If he can afford others he should certainly buy larger ones, such as Erichsen's standard Treatise, or he may with advantage resort to older works, to be easily got second-hand, of which Bransby Cooper's Lectures is a great favourite with us; but in such case he should be careful to compare each subject with the more modern doctrines of his new edition of Druitt. It is needless to multiply examples of this method of selection. A choice is offered on every subject. We have only to add that the student to whom expense is an object should confine his chief purchases to the subjects of the session. By this means he will, before his curriculum is over, accumulate many works which others have bought at an earlier period, and he will have had them at the time he most required them. He may also

deem it advisable to select one of the works most in favour in the school at which he enters, as some teachers make their lectures accord with a favourite manual.

There are several modes in which our report might be arranged. It would be easy, for example, to group the text books used at each of the several schools. Again, we might make a division according to the publishers by whom they are issued. Another plan would bring together the several books on each subject. Lastly, we might treat of them according to the period when the student is called upon to take up the subjects. No plan could be complete; and we shall therefore content ourselves with a combination of the two last-mentioned modes of arrangement. This plan will enable us first of all to devote attention to the text books on the subjects of the first winter session; but as we cannot give an accurate estimate of every one of them in this number, we reserve the others for further notice. The subjects of later study will follow. Before proceeding to these manuals, however, we take the opportunity of mentioning some books which the majority of students will find useful before entering upon hospital study. Those who have not yet absolutely decided their profession, as well as parents and guardians, should consult our last number. They may also advantageously read Mr. Baxter Langley's clear account of the profession entitled "Via Medica" (Hardwicke), a book which is likely to serve at many later stages of the medical life. If desirous of dipping still further into the habits and government of the profession, we can also commend to them the two Carmichael prize essays:—1. "The Medical Profession and its Educational and Licensing Bodies," by Dr. Mapother. 2. "Medical Education and Medical Interests," by Dr. Isaac Ashe, both published by Messrs. Fannin. Reference to the leading article in our last issue—the Student's Number—shows that not a few, at least in England, pass a preliminary pupillage, or apprenticeship, before the curriculum proper. In that early period study is equally important, and certain books are of great value. Thus, at this early stage the pupil becomes acquainted with drugs and chemicals, as well as other appliances of the medical art. Everyone in such a position ought to have the "British Pharmacopœia" constantly by him. That book he should be thoroughly familiar with, and works founded on it are of the utmost assistance to him. In the old time of the "London Pharmacopœia," Nevins's translation with notes was invaluable. It has not, however, we believe, been adapted to the new "British Pharmacopœia," the only authorised standard. The pupil will, however, hear of Squire's "Companion to the Pharmacopœia" (Churchills), and almost certainly find that excellent book in the surgery. We advise him to make it his constant companion, to examine what it says of everything he sees prescribed, and refer to it for anything which suggests itself to his mind for inquiry.

Owen's "Conspectus" (Longmans) is also a very useful work. It gives a tabular synopsis of the Pharmacopœia and of many non-official drugs and preparations, and is interleaved with ruled paper for notes. The student should fill those blank pages with notes and references, and so accumulate for himself a fund of information which is sure to be useful. We have had for some time on our table Lescher's "Introduction to the Elements of Pharmacy" (Evans and Co.). It contains in tabular form the outlines, not only of practical pharmacy, but of the sciences on which it is founded, viz., materia medica,

botany, and chemistry. Dispensing is taught in this work as well as it is possible to teach it in books; and the medical pupil or chemist's apprentice cannot err in following its directions. It is just such a book as we should have been glad of the first few months we entered the profession, and, further, it seems to us well adapted for apprentices to pharmaceutical chemists or to apothecaries.

We may now advance to the books required by the student in his first winter's session. He will hear the Introductory Lecture at the School he has selected, and each lecturer will also introduce his particular subject, and lay down his plans. The three leading subjects of the session, as laid down by all the corporations, are Chemistry, Anatomy, and Physiology. These are the foundations which are now to be laid, and that so broadly and well as to serve for future use. Surgery is also to be included in the course. First, as to Chemistry, inasmuch as many students know something of this fascinating science before entering a medical school. Those who do not should set to work in real earnest with the simplest and smallest manual, with a view of afterwards proceeding to a larger one. For this purpose none is better, if, indeed, any can equal, Professor Roscoe's "Lessons in Elementary Chemistry" (Macmillan). A new edition of this concise and accurate little text book has just appeared, and in it, for the small sum of 4s. 6d., the student gets all the important facts and principles of the science, and will have nothing to unlearn. It is so compact that it can be carried in the pocket continually without inconvenience. We should not recommend the pupil to proceed to the second portion on organic chemistry until he has not only mastered the earlier division—inorganic chemistry—in this volume, but has also gone over that part of the science in a larger work. Gentlemen who have not yet begun lectures and desire a book on Chemistry should get Roscoe's, which is also well adapted for schools where Chemistry is taught. Another very capital book for such a purpose, and one, too, that may be studied at the same time, is Galloway's "First Step in Chemistry" (Churchills), the last edition of which we reviewed on its appearance. It is particularly adapted for self-instruction. We hear that a new edition of the same author's "Quantitative Analysis" will shortly appear.

We now pass to the next sort of manuals. Those who can afford it could not do better than purchase Professor Allen Miller's magnificent work, now completed in three volumes, which have been successively reviewed at length in the MEDICAL PRESS AND CIRCULAR. Nor need the expense be all incurred at once, for the three volumes are sold separately, and the last on Organic Chemistry will not be needed for a long time. Dr. Miller's *Magnum Opus* contains all that is necessary to pass the various examinations, and to strive for honours in addition.

Many will, however, prefer a work that is more of a manual,—a single volume, not too large, and complete enough for all the medical student's wants. Fownes's "Manual of Chemistry"—one of Churchill's unrivalled series—has long held its ground as the favourite in many of the London Medical Schools, and it certainly fulfils the indications we have named. It is not, however, our most favourite volume of Churchill's series, every one of which we have successively purchased, keeping always a shelf of honour in our library to the most valuable set of medical text books ever issued by one house. This

probably arises from our *penchant* for a small and a large work, instead of one medium one. The pupil who buys Fownes' should also get another volume of the same series, that on "Natural Philosophy," by Mr. Brooke, founded on the work of Dr. Golding Bird. It is most important for Physics to be thoroughly studied as the preliminary to Chemistry proper, and we therefore name this companion volume.

Of Bernays' "Notes for Students in Chemistry," a new edition is in preparation, so that we may reserve a notice of that work, no books needing more constant revision than those on Chemistry. It is also rumoured in well-informed circles that Dr. Meymott Tidy, joint lecturer (with Dr. Lethely) on Chemistry at the London Hospital, has in an advanced state of preparation a new chemical text book. It is likely enough to appear before next year; and we anticipate that it will be one of the best manuals.

Williamson's "Chemistry for Students" is one of the Clarendon Press series, published by Messrs. Macmillan and Co., and is worthy of the reputation of the learned Professor at University College. The many students at the Birkbeck Laboratory will naturally select this as their manual. It possesses one of the greatest recommendations of a class book,—it is not too large. Professor Williamson has compressed his text book into rather less than 500 small 8vo pages, and yet, with all this condensation, there is no obscurity. It is, then, one of the briefest, and yet one of the most lucid, of the more important chemical manuals. Dr. Williamson's method is to describe and compare facts so as to lead towards general principles,—a mode of exposition which it would be well, in a practical study like this, to more generally employ. Of course, with this plan and in so small a manual, the author plunges at once into his subject, the book opening with directions for the preparation of oxygen. It is necessarily not easy, and its use should be preceded by a more elementary work. The student may carry this book almost constantly in his pocket without inconvenience. The new edition only came out last October. Students will require, in addition to this, a manual on Natural Philosophy. We have already named one (Brooke's) which will be found suitable in every respect.

Practical Chemistry forms the subject of a course in the medical curriculum distinct from the general course on Chemistry, and books may be advantageously consulted, not only during such a course, but even before the hospital career begins. Great progress may be made by study at home, provided a trifle be expended in apparatus and reagents. We have before us a very simple and useful guide for such purposes entitled, "Laboratory Teaching; or, Progressive Exercises in Practical Chemistry." It is by Professor C. L. Bloxam, whose name is a sufficient guarantee for its accuracy, and is published by Messrs. Churchill and Sons. It is all experiment, so to say, is illustrated by many woodcuts, printed in type that is particularly clear, and the edges are cut. It does not suppose any prior acquaintance with Chemistry, so that the very beginner may, with its aid, set about laboratory work; and, if he follow out its directions fairly, and perform all the experiments, he will be sure to make rapid progress. Being thus purely practical, of course all theoretical discussion is avoided.

So much for chemical text-books. We have next to

notice the other subjects of the first Winter Session—Anatomy and Physiology—but have not space in the present number for all. We may, however, open the subject by remarking that Physiology is already taught in a few schools, and therefore the pupil may have obtained some preliminary notice on the subject; if not, he cannot do better than begin with a work written for use in such schools as have introduced the subject. The best is one of Macmillan's School Series, called "Elementary Lessons in Physiology," and written by no less an author than Professor Huxley. It is an admirable illustration of how the greatest masters of a science may teach its elements in the most simple manner. As a matter of course, it deals only with the admitted truths of human physiology, the learned professor setting himself the task of presenting only such statements as are not likely to have to be unlearned; we would, therefore, strongly advise every one to make this the first book he reads on the subject. It is only necessary to read the first lesson to feel that the author has true teaching power in the highest degree.

The publishers have issued, in a separate form, a set of questions on Huxley's "Lessons," drawn up by Dr. Alcock, and which should be diligently used by the pupil. They will enable him thoroughly to digest his knowledge, and test his progress.

We must reserve our notes on the larger text-books on Physiology and on all on Anatomy to our next number.

(To be continued.)

SCOTLAND.

THE VACANT CHAIR OF PATHOLOGY.

OUR contemporary, the *Medical Times and Gazette* endeavours to lay down the law in regard to the above Chair, giving out as its opinion that if the Chair is to be one of general medicine, Dr. Sanders is the man; but if of pathology and morbid anatomy, then Dr. Stewart is pre-eminently qualified. It so happens that the Chair is one of general medicine; it combines the teaching of morbid anatomy and the principles of pathology *ex cathedra*, with the practical application of these principles in the wards of the Royal Infirmary. So far, therefore, and for similar reasons, we agree with our contemporary that Dr. Sanders is the man. But not for these reasons only. Apart from his unrivalled skill in the application of the principles of physiology and pathology to the elucidation of clinical facts, and the instruction of the students in the diagnosis and treatment of disease, Dr. Sanders is a pre-eminent pathologist and morbid anatomist. For sixteen years he has had the charge of one of the largest collections of morbid anatomy in the world, and, as we have already pointed out, has, by his pathological writings, modified and enlarged the views of pathologists in every part of the world. All this is amply borne out by his testimonials, which, besides an overwhelming amount of testimony from his own immediate professional brethren, comprise a greater number from distinguished pathologists than those of either of his opponents, and amongst them names of much higher standing and wider fame. Besides being a most distinguished practical pathologist, Dr. Sanders is unquestionably also an eminent clinical physician. The qualifications for the latter supplement but do not interfere with those of the former. To hint that they do, as our contemporary does, is even more un-

just than it would be to stigmatize Dr. Stewart as not a pathologist but a mere general practitioner; because, for the past few years, he has acted as such in partnership with one of our well-known physician-accoucheurs.

PROFESSOR SYME has forwarded the following reply to the Address of the Border Medical Association:—

1, Shandwick-place, Edinburgh,
Aug. 30th, 1869.

MY DEAR DR. TURNBULL,—I have received with more pleasure than it would be easy to express the kind expression of regard from so many of my respected brethren which you have had the goodness to transmit. Nothing could be more gratifying to me, and I beg that you will express to the members of your Association my best and most sincere thanks.

Yours very truly,
(Signed) JAMES SYME.

Dr. Turnbull.

SINGULAR RESTORATION OF SIGHT.—A strange story has got abroad in Edinburgh recently in regard to an aged female pauper in the St. Cuthbert's Poor-house. The woman has been an inmate of the poor-house for a good many years, and, in addition to her other misfortunes, she had that of being afflicted with blindness. Not long ago she was attacked with a very violent pain, such as the medical officers could not understand, far less relieve. It lasted for the whole of the night and part of the following day, and was described as of such a nature that it threatened to "tear her eyes out." At last it reached a height; the poor woman for a time was left in a state of semi-prostration; but to her delight, as soon as the pain had passed off, she found that her eyesight had been restored. One can imagine the astonishment of one of the officers, when, shaking him heartily by the hand, she said—"I have often shaken hands with you before; I have often heard your voice and spoken to you; but never have I seen your face till this morning." The case has caused some astonishment among the members of the medical profession in the city.—*Inverness Advertiser.*

OXYGEN.

EVERY method devised by which oxygen or oxygenized air may be cheaply supplied, possesses great scientific interest. Professor Graham, of London, has succeeded in increasing the amount of oxygen in the air by, as it were, filtering it through fine leaves of India rubber. By this treatment he has succeeded in adding thirty-six, forty, and forty-six per cent. of oxygen to the air. When air contains as high as forty-six per cent. of oxygen, it will reignite a glowing taper. This is a most important discovery, and, if practicable upon a large scale, must be of great service in the arts. Supply us with air containing forty-six per cent. oxygen, at trifling cost, and we have in our hands one of the most important agents of good it is possible to conceive of. With it we can add to our gas-lights a high degree of illuminating power, and, by promoting more perfect combustion, save immensely in fuel in heating our buildings.—*Boston Journal of Chemistry.*

AN OVARIAN CYST CONTAINING HAIR.

THE above was found by Dr. Paulicki, of Hamburg (*Wiener Med. Presse*, No. 40, 1868), in a woman of the town, aged twenty-three years. Her left ovary was found to be transformed into a number of cysts; one of which, on being opened, revealed a pale-yellow, fatty, glistening mass, of a pappy consistence, and a great number of brown hairs. The single hairs measured from two to five inches, and were somewhat thinner than the hair of the scalp. The cyst which contained these was of the size of a goose-egg. The left ovary had also numerous cysts; there were close adhesions between the uterus and rectum, and between the former and the ovaries and tubes. A radiant cicatrix was found in the vaginal portion of the uterus. Death had been caused by syphilitic erysipelas of the head.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, SEPTEMBER 22, 1869.

HOSPITALISM.

THE result of the interesting debate in the British Medical Association at Leeds has been to confirm us in the opinion we before expressed, that Sir J. Simpson has gained his cause; and that the system of large hospitals remains, after this, condemned by the verdict of all sound hygienic juries. There can be no doubt that Sir J. Simpson has proved, what indeed we might have early suspected, that superior skill avails but little against the baneful influences, whatever these are, which lurk within the walls of all large hospitals. The admirable operator, Nelaton, said once in our hearing in a lecture at the Hôpital des Cliniques, that he would not operate again that year in the hospital, since all his cases of amputations for some months had died of the effects of the wounds. Hence, we did not require much evidence in addition to this, to convince us of the truth of Dr. Simpson's assertions. We have, indeed, little doubt that large hospitals must be injurious also, to a great extent, in the treatment of fevers, or of any chronic medical disease, such as bronchitis or pneumonia; and we have no intention of invoking any of the various theories to account for the first, such as the propagation of germ cells, or the floating about in the air of pus cells, &c. As in most other cases in medical research, the *theory* is not what it is important to be certain about: it is the *law of nature* we desire to recognise. Now, it is clearly and incontestably proved, we believe, that, just in proportion as the hospital is large, so is the amount of mortality large, of course, *ceteris paribus*.

“Well,” our objectors will say, “granting your data, does it follow that we are to have no more large hospitals for the sick?” We answer, “Certainly it does follow; there is no inherent necessity for any such large hospitals to exist, that we can see.” The question of expense is a ridiculous one; as if there could be any saving in the idea of an establishment for the sick calculated to prolong

their sufferings and convalescence. Such a supposition could only be tenable when the sick belonged to a hostile nation, whose tenor of existence we desired to make as weak and fragile as we could, by cunningly devised means. That we ourselves should talk about economy in questions relating to health and existence is, of course, an absurdity. At least, it will be seen to be so when this merely evanescent state of industrialism shall have gone by, and left us time to find out that to have a healthy and happy people ought to be the great religion of the State. The evils of the large hospital system have long been known even to many of the Parisian medical faculty, who have a far greater excuse than we have for ignorance of the evil effects of large houses, full either of sick or of healthy human beings. Has it not always been our boast, that we live, each one in our own houses; and that, following the saying of the immortal Socrates, our houses are "small and full of friends," whilst the French have been brought up in enormous *hotels* from their earliest years, and have never, indeed, known what it is, especially in Paris, to dwell in a moderately sized dwelling-house? We have long thought that the sole reason of the comparatively lower death rate of London resides in the unhygienic habit of the Parisians in living in such large and palatial edifices. And Levy, in his admirable work on hygiene, thoroughly recognises the superior advantages which our small dwelling-houses confer upon their inmates in the matter of ventilation, of convenience, and of privacy. And yet, with all this before us, we have, hitherto, so far forgotten all these considerations, as to heap together crowds of sick persons in our large hospitals, such as St. Bartholomew's, Guy's, or St. Thomas's, and Middlesex. The past is beyond our control; but in future let us hope that no more money will be wasted, as is being done at present in constructing palaces like the new St. Thomas's Hospital, or the new *Hôtel Dieu* at Paris, or the Poor Law hospitals. Such buildings but insult our ideas of propriety, instead of raising emotions of admiration. It is said, indeed, of the new *Hôtel Dieu* in Paris, that, if bedrooms were hired for the patients in the most expensive quarter of Paris, they could nowhere be so expensive as the estimate for this immense building shows that they are about to be. And then, after the new St. Thomas's Palace, and the new Palace *Hôtel Dieu* are built, we shall, of course, speedily hear of the ill-success of the operations in both of them; as we have long heard of the deadly character even of the *Hôpital Lariboisière*, with all its splendours. Our idea is that a street or two of ordinary small houses, of one or two storeys high, would be far more suited for the cure of patients, whether medical or surgical cases, than the present hospitals are. And, again, all that has been said in favour of placing hospitals in the neighbourhood of the poor people who require them, will never convince us that, except in the cases of very acute diseases and accidents, the majority of hospital cases would not do far better if removed a few miles out of town. Would not we ourselves, if suffering from any chronic complaint, infinitely prefer giving ourselves the chance of country air and tranquillity, instead of remaining in the midst of bricks, mortar, cabs, omnibuses, and barrel organs? The Prussian army's experiments settled the question some years ago. It remains only for us to carry out the system so admirably elucidated by that experiment, and by Sir J. Simpson's comparative statistics. We almost suspect, however, that so many professional

interests are opposed to this new plan, that it is the public, not the profession, that will be the first to move. And we are going to prophecy—a most unwise action in all cases, but more especially so when it is based on any hopes as to sudden changes in British public opinion—that the form in which the alteration from large to small hospitals will be brought about, will be by the public becoming less ready to subscribe to the larger hospitals, and commencing to encourage small and suburban residences for the sick. The great triumph of the hydropathic practitioner has always ended in his withdrawal of his patients from the air of crowded cities; and there can be no doubt in the mind of any true physician that this has constituted a very great part of the acknowledged efficiency of that system of natural medication. Why should we not take a lesson from all these facts, and unlearn the lessons we have been taught, as to the necessity for walking large hospitals in order to learn how to cure the sick? Doubtless mechanical dexterity in operations is most rapidly acquired in such places; and the rapidity with which death succeeds death renders the study of dead-house pathology more easily obtainable; but surely, after all, even these must pale in importance before the grand object of all human science, the advancement of the health and happiness of ourselves and our neighbours.

One thing has lately struck us with sorrow, and that is that we have recently noticed in some parts of London a tendency to imitate the street architecture of Paris. The magnificent appearance of Paris is dearly purchased, in our opinion, by the enormous size of the houses recently built by the order of M. Hausmann. Those who have inhabited such houses, with their narrow courts in the centre, and have observed the want of air of the chambers built around their deep courts, especially near the basement storeys, will agree with us in our lamentations. Besides this, persons who inhabit the upper storeys in such lofty houses, especially women, generally far too fond of the house, are tempted to remain within doors incessantly, from the great fatigue necessitated by the dragging upstairs of all their articles of food, &c. As to "lifts," too, they are, we hold, always more or less dangerous, and not to be thought of as a substitute for small houses with their many conveniences. Underground railways have now solved the difficulties about removing persons into the country. In fact, there are now scarcely any objections against a change, and we hope a change may soon take place.

Notes on Current Topics.

Indigenous Foods in India.

DR. MOORE, the Superintendent of the Raj Dispensaries in Rajpootana, notes the following aliments in use among the inhabitants of that country during the late season of scarcity (1868):—

"Atta being scarce and expensive, I found the inhabitants of Rajpootana use the following materials, ground up and mixed with various proportions of flour:—The roots of a peculiar coarse grass called *Nagoo Moth*, found growing near tanks, jheels, and wells. Of this there are two varieties, one sweet and soft, consumed by the people; the other hard and pungent, and given to cattle.

"2ndly.—The long roots of a rish, or cyperus, also found in the beds of tanks. This contains a large mass of pithy substance, looking like coarse arrowroot.

"3rdly.—The kernels of the wild plum, where it grows, as, for instance, in Shekawatty.

"4thly.—The inner bark of the tamarind and neem trees. The two latter substances are not used except as a last resort.

"5thly.—When produced, the kurree or linseed cake, formed of the seeds after removal of the oil.

"Thus the country supplies a larger amount of aliment than could have been supposed."

The Contagion of Dog Mange.

THE etiology of *tenia favosa* in man may be regarded as decided by M. St. Cyr, of Lyons, who put beyond doubt its transmissibility from animals to man.

The presence of mangy dogs in the Veterinary School at Lyons has produced a true epidemic amongst the mice. Three pupils of the school have submitted themselves to the contagion, and solution of corrosive sublimate in glycerine has been found to be almost a specific.

Deaths of Passengers on Indian Railways.

In the note prepared by the Government on the returns of accidents on railways during the year 1864, it was remarked—"There is a class of casualty to native passengers which, as it has nothing to do with the working of the trains, does not appear in these returns. The number of persons found dead in trains is very large, especially in the north-western division of the East Indian Railway. These casualties are attributed by the railway authorities to the hot winds and great heat, and to the pilgrimages to the Ganges being undertaken by persons physically unfit for the fatigue of travelling; but the suspicion of unfair play may not be without foundation, and the railway traffic establishment and the police may have a responsibility in the matter."

In the *Indian Medical Gazette* of the 1st March, 1869, the number of deaths of this kind on the East Indian Railway was prominently noticed, as also the insufficient means of affording medical aid to railway passengers at the Jumalpoor station.

The reply of the Government of Bengal establishes that the statements made in the *Indian Medical Gazette* are not altogether correct, but the number of deaths which actually took place on the East Indian Railway are quite sufficient to justify the object of the writer, viz., to attract attention to the subject.

The deaths, it is conjectured, resulted chiefly, if not entirely, from the very natural desire which natives, when ill and away from their homes, have of returning to them, although unfit to bear the fatigues of the journey.

As remarked by the Government of Bengal, such cases can scarcely be provided against, for when an intending passenger tenders his fare, the railway company is bound to carry him so long as there is room. If, however, it should appear on further observation that persons are frequently put into trains in a dangerous condition of health, this may afford an additional reason for adopting a suggestion recently received from the Government of Madras for providing, by an Act of the Legislature, that persons suffering from infectious or contagious diseases should be carried on railways in special carriages only. Such a power of controlling the traffic might very probably have the effect of reducing the number of deaths on railways; but, on the other hand, it is observed that of the classified causes of death given by

the Government of Bengal, only five are due apparently to contagious diseases. It has to be noticed, however, that in a large number of the cases, 23 out of a total of 53, the causes have not been specified.

The larger number of deaths on the East Indian and Great Indian Peninsula Railways is certainly striking; on the former there were 105 deaths, and on the latter 74 for every ten-million passengers during 1868. On the Madras Company's lines there were only 23, and on the Bombay, Baroda and Central India Railway, 24. The figures for the other railways are comparatively small. Taking them together, the corresponding number obtained is 22.

The Nerves of Deglutition.

MESSRS. WALTER and PREVOST have communicated to the Paris Academy a note, of which the following are the conclusions:—

1.—The *glosso-pharyngeal* contributes nothing, in the rabbit, to the reflex function of deglutition.

2.—The *trigeminal* animates the *velum palati*, and is the principal sensitive presiding over deglutition; after the section of one of these nerves it is no longer possible to excite the corresponding half of the palate.

3.—The *superior laryngeal* contributes to deglutition by animating the mucous membrane of the epiglottis and the neighbouring parts.

4.—The *recurrent* also contributes by sensitive branches which it sends to the upper part of the œsophagus. Electric excitation of it produces rhythmical movements of deglutition and the arrest of the diaphragm in expiration.

Electrisation of the superior laryngeal has frequently produced cough in the dog and cat, but it has never caused vomiting, which is easily produced by excitation of the central root of the *vagus*.

The London Hospital.

MESSRS. J. MACARTHY, Sheffield, Davy, and Reeves, are candidates for the assistant-surgeons at this hospital. There have been many changes at the London of late years, and several are now on the staff who were not educated at the school. It is perhaps time that this liberality should be seasoned with a due regard to the interests of London Hospital men, who are at a disadvantage elsewhere, in consequence of the common practice of giving a preference to the pupils of an institution. We hope on this occasion the best London Hospital men will be elected.

While on this subject we may repeat what we stated a little while ago, that no hospital presents a larger field for acquiring practical knowledge. A pupil who enters there and is diligent is sure to have appointments—without fee—which he may both pay and wait in vain for at other schools. The work is, in fact, so large, that there is always employment for more than those gentlemen who are on duty. Really, with such enormous pressure the Governors should consider the propriety of effecting another increase in the staff. In the interests of the patients this would be a wise step.

Sanitary Condition of Calcutta.

A "Report on the Drainage and Conservancy of Calcutta," by Dr. Smith, the Sanitary Commissioner for Bengal, has been issued. It discloses the cloacal condition

of the atmosphere, the filthy habits of the people, the want of drainage and of efficient conservancy, and is couched in language so strong as to have called forth unfavourable comment from a portion of the Calcutta Press. But whether the stinging strictures of the Sanitary Commissioner be received in a spirit of humility or intolerance, the facts must be accepted and laid to heart by Government and the Calcutta Municipality. These facts are, that Calcutta is an unsafe, unsuitable, and unhealthy place of residence; a hotbed of cholera, in consequence of defective scavenging, the accumulation of putrefying night-soil, and the filling up of "hollows, broken ground, and even tanks, with the sweepings and off-scourings of the city;" that "wilful pollution of the river Hooghly" above the shipping is practised by casting the night-soil into the stream;" that the compound closets are obnoxious and revolting; the Melter Depots are almost unapproachable; and the private closets are built upon ground soaked with ordure, and surrounded by an atmosphere overpoweringly fetid. That the sweepings are so disposed of as to contaminate the atmosphere for long distances on a line of traffic.

The Mortality of Cholera.

It is a terrible fact, that, of the steady increase of the rate of mortality among cholera patients during the last thirty years, from twenty-five to sixty-five per cent.—terrible, not merely in relation to this special disease, but because it must tend, more or less, to cast a doubt on our modern system of medicine in general. The *Indian Examiner* says, that the Profession are agreed that this increased mortality is due to our altered treatment, and not to any change in the type of the disease itself. And if it is beyond doubt that thirty years ago our treatment of cholera saved three-fourths of those attacked, and that since then we have been wandering gradually further from success, it seems incomparably the safest course to go back without hesitation to the treatment of thirty years ago, and begin our lesson over again. It cannot be a very difficult matter to ascertain how cholera was treated thirty years ago. Here is our known point of departure, and there is no difficulty in returning to it. It is nearer to our goal than our present position by forty per cent. It may be possible to discover the precise direction in which we have erred; but it is better to return, than to speculate on possibilities.

Dr. Murray is strongly of opinion that it is the use of alcoholic and other stimulants which has led to the increased mortality; and certainly his figures prove that our retrogression has been *pari passu* with this innovation. He is probably right; but this may not be the whole truth.
